Albuminuria, the pathology and relations of, by Dr. W. H. Dickinson, 355, 399
Alcohol at the Medical Society, the debate on, 49, 139
Alcohol in therapeutics, Dr. Richardson on, 33
Alexander memorial fund, 395
Althaus, Dr. J., contribution to the etiology of nervous diseases, 375
American medical centennial celebration at Philadelphia, the, 35
Amputation of the female breast, a case of, by Mr. W. H. Middleton, 380
Anæsthetisation during sleep, 307
Aneurismal hæmorrhage from a diseased lung, case of, by Mr. Kendal Franks, 194
Aneurism of the arch of the aorta, 260, 261
Animal vaccination, for and against by Dr. C. R. Drysdale, 41, 66, 85, 193
Antiseptic power of salicylic acid and certain of its compounds compared with other antiseptics therapeutically considered, on the, 406
Antiseptics, the use of, 301
Anti-vaccination, 271
Anti-vaccination craze, 509
Anti-vaccination league, the, 73
Anti-vivisectionists, curiosities of the, 453
Anti-vivisection publications, 268
Anti-vivisection societies, 228
Antivivisection Society, the, 534
Apomorphia, dangers of, 37
Appointments, 17, 39, 61, 84, 105, 127, 149, 192, 212, 232, 252, 272, 292, 313, 332, 353, 395, 417, 438, 458, 478, 520, 540
Army and navy, cooking for the, 75
Army, foreign surgeons for the, 434
Army, the health of the, 13, 403
Army Medical Department, 148, 204; reorganisation of the, 224; royal warrant, 380
Army medical officers, 222, 280, 539
Army medical reports, 33; for 1873, 120; for 1874, 411
Army medical scheme, the, 230
Army medical school, 280; at Netley, the, 309
Army medical selections, 265
Army medical warrant, the, 442
Arnica, the healing element in, 56
Arsenic, detection of, 211
Arsenic, experiments with, 472
Arsenical wall papers, 326
Artificial milk, 93
Artisans' dwellings, 123
Ascaris lumbricoides, 261
Assessment of St. Thomas's Hospital, the, 204
Assimilative food, on, by Mr. W. J. Cooper, 195
Assumption of medical initials, 58
Atmospheric germ theory of disease, 200
Attorney doctors, 251
Ashe, Dr. I., medical politics (*Review*), 60
Asylum accommodation in Ireland, insufficiency of, 13
Atthil, Dr. Lombe, removal of an ovarian cyst, 527

B

Baker, Mr. T., on the causes of epidemics, 89, 133
Balham, a mysterious death at, 433
Barton, Dr. J., a case of spinal injury, 63; case of lithotomy, 234, 236
Beastings, 12
Begbie, Dr. Warburton, 190, 210
Bennett, Mr. E. H., the modes of using carbolic and salicylic acid in antiseptic surgery, 295, 301
Benson, Mr. J. Hawtrey, case of cardiac disease with embolism, cerebral softening, and aphasia, 217
Bentley and Trimen's medicinal plants (*Review*), 310
Betts v. the "Medical Press and Circular," 35
Biennial retrospect of medicine and their allied science, for 1873-74, (*Review*), 291
Biliary colic, by Mr. T. Hayden, 316, 424
Bills before Parliament, 231
Bills for the amendment of the Medical Act, the, 263
Bill to amend the Medical Act, 1858, a, 168
Bill to remove restrictions on the granting of qualifications for registration under the Medical Act on the ground of sex, a, 462
Birmingham sanitary work, 367
Birth-rate of Dublin, the, 345
Births, 128, 149, 192, 232, 292, 313, 322, 353
Blake, Dr. C. C., zoology for students (*Review*), 331
Boeck, Professor, of Christiania, death of, 14
Books, pamphlets, and medical journals received, 17, 61, 105, 149, 212, 232, 272, 292, 332, 375, 417, 478
Borax, 226
Border-land between animal and vegetable life, 125
Bouchardat's, Prof., rules for glycosuric patients, 34
Boulevards in London, 226
Boulogne-sur-mer, 538
Brain-workers, longevity of, 345
Braithwaite's retrospect of medicine (*Review*), 270
Branch Medical Council (Ireland), list of entries in the register of

the, for the month of April, 1876, 478
Brand's preparations of meat, 99
Breast, how to strap the, 83
Brighton and the British Medical Association, 205
British Home for Incurables, 251
British Medical Association, the, 286, 538
Browne, Dr. Crichton, 283
Brussels Hygienic Exhibition, 493
Budget and the profession, the, 306
Bulbar paralysis, 219
Burrows, Sir John Cordy, 271, 432; posthumous honour to, 286
Butter, conversion of, 98

C

Cairns, Prof., the character and logical method of political economy (*Review*), 207
Cambridge University, 539
Camphor poisoning, 37
Cancerous ulceration of the tongue following lingual psoriasis, 247
Cane fund, the, 249
Capillary bronchitis, 208
Carbolic acid as a local anæsthetic when the actual cautery is applied, 458
Carbolic and salicylic acids in antiseptic surgery, the mode of using, by Mr. C. H. Bennett, 295, 301

IMPAIRMENT, OR LOSS OF VISION, FROM SPINAL CONCUSSION, OR SHOCK. (a)

By Jabez Hogg,

Surgeon to the Royal Westminster Ophthalmic Hospital, &c.

(*Continued from p. 531 of last Vol.*)

Case X.—*Railway Injury—Rapid Development of Symptoms—Cataract—Retino-Choroiditis.*—Mrs. S., æt. 60, was riding in a second-class railway carriage on the North-Eastern line, March, 1871, when a collision occurred, and she was thrown with considerable force against the opposite side of the compartment. She was stunned, shaken, and her forehead much bruised. She became nervous, and out of health, and remained under medical treatment for some weeks. Up to the time of the accident Mrs. S. had been a good business woman, had successfully conducted for some years a pawnbroker's shop, but was now quite incapacitated, indeed, could not see to read, and barely write her name, and could no longer conduct her business. In March, 1872, I was requested to see her in consultation with Mr. Welford, of Sunderland; she required at this time assistance to get about ; the left eye was cataractous, sight was totally obscured, and in the right large quantities of pigment were seen moving about, retino-choroiditis, threatening total blindness. Mr. Welford, who had attended Mrs. S. for some years, had not noticed cataract ; on the contrary, he always believed she had good sight, for she had not required glasses. I attributed her loss of sight to the blow on the forehead, which affected the nutrition of the eye, was in fact the cause of the pigmentary retinitis through implication and irritation of the fifth nerve.

Mr. Welford has lately furnished me with further particulars of Mrs. S.'s present state. It appears that when at church one Sunday evening in September last she was seized with sudden blindness of the right eye. Although feeling poorly and fatigued she insisted upon going to church, where she suddenly saw "a black-pall fall down before her eye." The next morning she could not tell whether it was day or night. The pupil was much contracted. Iodide of potassim in 5-gr. doses, and tincture of belladonna 5 drops three times a day was continued for a month, when sight began gradually to return, for she saw the hour by the clock, and could distinguish coin, a sovereign from a shilling.

Case XI.—*Railway Injury producing Anæmia of the Cord—Hysterical Spine—Partial Recovery.*—Mr. W. H. M., æt. 38, a post-office travelling clerk, in a collision, June 28, 1871, between Derby and Newcastle. He was at the moment occupied at his desk, when he was thrown forwards and backwards, falling flat on his back. He soon recovered his feet, and although shaken, was able to proceed on his journey. It was not until after his return journey to Derby he discovered that his back was much hurt ; he was passing a large quantity of pale-coloured urine, and his bowels were confined ; had suffered from piles. Mr. Fowles, his ordinary medical attendant, made a careful examination of his person, and found several bruises about the lumbar region. He then complained of headache, giddiness, loss of sight, and palpitation of the heart, which confined him to his room for three or four weeks, when he was seen by the medical officer of the railway company and also by Dr. Waller Lewis, who recommended rest, sea air, &c. No change occurred, however, in his symptoms ; he was frequently subject to violent attacks of palpitation of the heart, and was very hysterical. Dr. Lewis again saw him in consultation, and reported him unfit for duty.

His impaired vision had caused both himself and wife considerable anxiety, and on the 19th of August he consulted me. I learnt that three years previously he had been an unfortunate victim in an accident near the Camden Town Station, and since then had suffered from almost constant headache and sleeplessness. He was often unable to control his movements, and had therefore been obliged to constantly resort to narcotics. Manifest hyperme-

(a) A paper read at the Medical Society of London, Nov. 8th, 1875.

tropia was present in his case, and he required + 36 glasses to neutralise it; even then he was unable to read for more than a few minutes without fatigue. This power was increased to + 18, and about the same time hyperæmia of the retina was observed. He now appeared to be suffering from considerable functional disturbance, was extremely hysterical, and indulged in fits of crying. The impairment of vision I thought in some measure due to the hysterical symptoms, and ventured to predict his ultimate recovery. On inquiry a few weeks since, and nearly five years after the accident, I was informed that Mr. M.'s hysterical condition much affected his general health, and that during the year 1871 he was off duty, on sick leave, 139 days. In 1872 he was in another slight accident on the Midland Railway, and was off duty 186 days. In 1873 he was off duty 52 days; in 1874 he was only away during the usual official holiday; and in 1875 was away on sick leave for 74 days. I look upon his case as a good example of hysteria or anæmia of the spine.

CASE XII.—*Tramway Accident—no Direct Injury to Head or Spine—Gradual Development of Symptoms—Palsy and Anæsthesia on one Side; Hyperæsthesia of the other—Slow Recovery.*—Mr. W. B——, æt. 34, on the evening of the 16th of January, 1874, was on his way to an evening party when the brougham in which he was riding was caught by a tram-car, and turneed over. Mr. B. was riding with his back to the horse, his two sisters sitting opposite to him, and when extricated was lying under them. They were all taken out through the window, and as the accident occurred close to the friend's house they received immediate attention. After a short interval of rest Mr. B. felt able to join in the dance, which was kept up until three in the morning. He returned home, and although feeling a little bruised and sore, he went off as usual to business. In the course of the afternoon, and about eighteen hours after the accident, he felt ill, pains in his limbs, numbness in the right hand, and a feeling of nausea. On the following day, the 19th, these symptoms increased, and in addition he experienced difficulty in swallowing, with severe pains about the lower cervical and upper dorsal regions. The right hand became paralysed and anæsthetic, while the left was hyperæsthetic. He felt every breath of cold air, even moving the bedclothes produced a shudder—"a feeling as if scalded ice was touching him." On the 20th he lost power over the right leg, and the palsy appeared to be gradually creeping over him; the sphincters were unaffected. His condition at the end of a week was pitiable and alarming in the extreme, and I was requested to see him in consultation with the family attendant Mr. Llewellyn.

I found Mr. B. lying in a perfectly supine position, breathing hurriedly, and scarcely able to reply to my questions; he was very hysterical, and sobbed when I asked him to give me his hand to feel his pulse, he was conscious of being unable to raise it. He answered with considerable hesitation, and spoke in a low feeble voice. The temperature of the two extremities differed as much as two and two and a-half degrees, that of the right being 90°, and the left 92½°. He complained of great pain in the head, and which extended down to the shoulders; his head required to be supported on either side by pillows; hearing on the right side was much duller than on the left, indeed, the loss of sensation on this side was very marked. Full doses of morphia were required to allay pain and secure sleep.

On my attempting to examine the eyes with the ophthalmoscope the ray of light from a candle produced lachrymation, photophobia was intense, and I was obliged to desist. There was no paralysis of the sphincters; his brain was bright and clear, and he pressed me to tell him whether I considered him in much danger. We insisted upon perfect rest, ordered nourishment and stimulants to be constantly administered, and prescribed full doses of iodide of potassium.

Ten days afterwards I again saw him, and heard that Dr. Moxam had in the interval been called in, and concurred in the treatment. He was now slightly better, could, with some effort, move his right foot; there was less lachrymation and intolerance of light, and I was able to examine the internal eye. The disc and fundus of the right was much inflamed, and on the outer peripheral margin several capillary hæmorrhages were seen. The fundus of the left seemed to be obscured by some opacity, probably of the vitreous, inflammation of the vitreous body. The light, however, much distressed him, and I was obliged to desist; vision was certainly not so good in this eye.

Ten days elapsed before I saw him again, when he was more cheerful; could move his right leg and hand; the tenderness about the cervical region had much subsided; sleep was more natural; the removal of the bed-clothes no longer gave annoyance. Bowels a good deal constipated, doubtless from the quantity of morphia administered; on the whole satisfactorily progressing.

Ten weeks after the receipt of injury I again saw him; he was then lying on a sofa near the fire; could bear removal daily from bed; the extremities were fast recovering sensation, and he was able to raise his right hand and arm; hearing was improving, and he could rotate his head without causing pain; was still unable to sleep without morphia.

Clinical Records.

DIVISION OF THE EXTERNAL LATERAL LIGAMENT OF THE KNEE. (*a*)

By Mr. J. E. KELLY,

Surgeon to the Jervis Street Hospital; Professor of Anatomy and Physiology, Ledwich School of Medicine, Dublin, &c.

As this operation, proposed by Langenbeck, and performed by him, Bilroth, and others, is comparatively rare among us, the following cases may be interesting.

Genu valgum, or knock-knee, when existing to a high degree, is notably intractable to minor orthopædic treatment. The firmness of the joint and the difficulty of applying efficient pressure in an advantageous direction constitute such formidable obstacles that any addition to our resources should be most welcome. A cursory glance at the mechanism of the deformity will clearly show the advantages of Langenbeck's operation. Like the other distortions due to the disturbed growth of bone or modelling pressure, it generally commences before puberty, and presents the same series of phenomena. Waving the question of the causative association of rachitis with this deformity, when a child begins to walk it widely separates its feet in the effort to maintain the erect posture; the structures on the inner side of the knee are necessarily strained, and if they are deficient in normal tonicity or resistance, they yield. Their extension is associated with a corresponding relaxation of the structures on the outside of the joint, which quickly adapt themselves to this condition by permanently contracting. Diminution of the tibio-femoral angle is consequent on the separation of the inner condyles of the femur and the tibia, and all the weight of the body is borne by the external condyles, until the entire articular surfaces are again allowed to coincide by the process of modelling pressure affecting the young bone. Thus is the deformity rendered permanent, and it is also progressive, as, in proportion to the diminution of the tibio-femoral angle, the influences which caused the lesion become more favourably circumstanced for manifestation. An additional distorting force is introduced by the direction in which the biceps femoris and the other muscles of the outer group act when the deformity is established.

The first factor in the production of the deformity is relaxation and contraction of the internal and external lateral ligaments respectively, together with the neighbouring structures; the second, the modelling pressure on the

(*a*) Read before the Surgical Society of Ireland, Dec.

bones; and the third, the action of the external group of muscles. The treatment of the disease rationally aims at reversing the first and second of these factors, and removing the third. By section of the external lateral ligament its artificial relaxation is obtained, and the internal ligament is allowed to contract; the judicious application of mechanical apparatus reverses the modelling pressure by removing it from the outer to the inner condyles; the division of the tendon of the biceps removes the principal disturbing muscular force.

I have subcutaneously divided the external lateral ligament four times in three patients. I shall briefly communicate the interesting details of these cases :—

CASE I.—John ——, æt 4, a very delicate child, might well be described, as Scarron summed up his own deformities, as resembling the letter Z. He was unable to walk except when clutching a stick or some person's clothes. He had genu valgum on the right side and genu varum on the left; his pelvis was oblique, and he had well-developed scoliosis, or lateral spinal curvature. The distortion commenced in the right leg, and was detected shortly after the child commenced to walk. In a little time the left leg became affected, and the spine curved; both of those were evidently compensatory to the primary distortion. My first efforts were directed towards mechanical treatment, but the results were negative. I then divided the external lateral ligament of the right knee, and reapplied the same apparatus which had been so ineffectual previously. The child quickly acquired the power of walking, and continues to improve daily. The limbs have become muscular, and when he played with his brother I have confounded them more than once, until a direct examination of the limb enabled me to recognise my little patient.

CASE II.—Mary ——, æt. 14, of a heavy leucophlegmatic temperament, may be regarded as a most unfavourable subject for such an operation. I divided both external ligaments, and applied a double apparatus. The accompanying woodcuts, taken from photographs in my possession, convey the best idea of the case and the results. She can now run up and down stairs, and is as active as most girls of her age and temperament. By the operation her stature has been considerably increased.

CASE III.—James ——, æt. 12, had recovered with ankylosis from suppurative articular inflammation. Although the case was one of little promise, I operated as a measure preparatory to subsequent mechanical treatment. The case passed from under my care, but I am satisfied the indication, if properly applied, will be most useful.

The section of the external lateral ligament is made close to the head of the fibula, where, typically, a space intervenes between the adjacent synovial membranes of the knee and of the tibio-fibular articulations. This space is sometimes obliterated by the communication of the two synovial cavities. When it exists it is bounded above by the synovial membrane of the knee-joint, below by that of the peroneo-tibial articulation, internally by the external surface of the condyle of the tibia, and externally by the external lateral ligament and the closely-associated tendon of the biceps femoris. Across the space, and in the track of the knife, passes the inferior external articular artery, and closely along its posterior margin runs the external popliteal nerve. The penetration of the knee-joint does not appear of any moment in the operation, as, at least, in some of the cases on record, in fact, in all, unless this space is selected, it must have occurred without any record of special symptoms arising during the course of the convalescence. In one case, owing to the free hæmorrhage, I am satisfied that the above-mentioned artery had been divided. In this instance nothing unusual manifested itself. The third structure meriting special mention is the external popliteal nerve, which, I need hardly say, lies close to the tendon of the biceps muscle, behind which the knife enters. A little practice will educate the touch to recognise the nerve as it slips from under the finger. Immediately as the nerve slips away, the knife must be entered boldly and carried down almost to the surface of the tibia, and then pushed forward until its point projects under the skin, when the section must be made. If the knife be not passed deeply the strongest portion of the ligament will be left intact. A slight lateral movement will test the efficiency of the section, and if it should be found insufficient, the operation may be immediately completed, or postponed for a short time. Remembering the proximity of the external articular artery, and with a view of preventing hæmorrhage into the knee-joint if the latter should be opened, I am in the habit of binding a narrow pad very firmly along the course of the incision. In my earlier cases I applied ice most sedulously for a few days, but I have ceased to regard it as a necessary procedure. Four or five days after the operation the splints may be applied. With regard to the mechanical apparatus, very few points merit our attention, owing to the simplest being most efficient. Fixity in a position exactly subtending the tibio-femoral angle is the main point; the slightest lateralisation immeasurably lessens the utility of the apparatus, or renders it absolutely useless. I have attained this important object by the use of the ordinary pelvic girdle and a socket in the boot, a little anterior to the heel. The connecting bar may have an ankle and hip hinge, but it must have none at the knee, as the slightest flexion of the knee-joint enables the patient to evade pressure. If rapid extension of the limb were important, it might be attained by the division of the resisting bands of the fascia lata, especially of that serving as the point of attachment for the tensor vaginæ femoris. It may be desirable, except in extreme cases, to retain these powerful connecting structures, and they are useful in directing the mechanical force or pressure to the inner condyles.

THERE were an extraordinary number of accidents necessitating surgical interference in London last week; in three days no less than 50 serious accidents were taken to St. Thomas's Hospital alone.

DURING the year now closing some rare examples of old age have been recorded, says the *Standard*, among the Fellows of the Royal College of Surgeons of England, four having died whose united ages amounted to 376 years, thus giving an average of 94 years to each persor. Their respective names and ages were as follows :—R. Stanley Ireland, of Dublin, 96, diploma dated June, 1801; James Snow, of Lincoln, 95, April, 1802; James Dawson, of Ambleside, 95, February, 1805; and Henry Franklin, C.B., Inspector-General of Army Hospitals, 90, February, 1812.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE Society held its second meeting on Friday, the 10th of December, at the Royal College of Surgeons in Ireland, the President of the College in the chair.

Mr. J. E. KELLY read a communication on

DIVISION OF THE EXTERNAL LATERAL LIGAMENT OF THE KNEE,

which will be found at page 2. In the succeeding discussion,

Dr. M'SWINEY said he thought it was due to his colleague to say that he had the advantage of seeing one of the cases before the operation, when the deformity was fully as great as it was represented in the woodcut. He was also present at the operation, and saw the girl some eight or ten months after it, and the improvement was fully as great as shown in the woodcut. Judging from the case, he saw nothing that could be more complete or satisfactory than the operation was.

Dr. ROBERT MCDONNELL said he did not rise with the view of discussing the paper read by Mr. Kelly. He desired to say that he also had had an opportunity of seeing the case, not before, but after the operation, and he must say that the result was extremely satisfactory. The limbs were quite straight, and the woodcut gave a correct and truthful idea of the improvement which had taken place. The account he got of the case and the examination he had made quite satisfied him with regard to the advantages of the operation,

The PRESIDENT remarked to Mr. Kelly that there was nothing to reply to, and Mr. Kelly being of the same opinion,

The PRESIDENT, before calling on Dr. Haughton to read his paper on "Suspension," said that as the communication would occupy more time than was allowed according to the rules of the Society, he would ask the members to suspend the standing orders in order that he would not have to interrupt Dr. Haughton.

The standing orders were accordingly suspended.

Dr. HAUGHTON then inquired whether there were any reporters of the daily public press present, as if there were he would have to decline entering upon the subject of his paper.

Mr. WILLS RICHARDSON replied that there were no reporters present except the one appointed by the Society.

Dr. HAUGHTON said his reason for making inquiry was that he had been asked by several societies, both in London and Dublin—and it would be no dishonour to this Society to say that they occupied a higher position than it did—to read this paper before them, and he had refused, on the ground that he would not be made the instrument of gratifying a morbid curiosity. He wished emphatically to say that his paper would never have seen the light if it was not that he was persuaded that this was a proper audience before which to lay it, and that his reading it to-night might serve in the future some important ends.

ON A COMPARISON OF THE ROPES WHICH HANGED KILKENNY, CARR, AND MONTGOMERY, WITH PRACTICAL DEDUCTIONS THEREFROM.

The Reverend Professor HAUGHTON, F.T.C.D., F.R.C.S.I. (*Hon. Caus.*), said—There was no young man entering the medical profession, and seeking his career in the army, as was very well known to many around him, that might not be called upon at any moment, in a colonial dependency or foreign country, by his commanding officer to see that an execution was carried out in a humane and proper way; and he could see nothing more distressing or painful than the position of the young medical officer called upon to superintend a scene of that kind without rudimentary knowledge of such matters. But he felt also bound to bring forward the paper before the Society on that evening because of the lapse of time—five years—which had occurred since a very distressing event in their city brought a distinguished member of their profession—Mr. Minchin—into a position in which strong public comments were made upon him. He (Dr. Haughton) proposed to publish in his paper for the first time after this lapse of time the report which he, at the request of Earl Spencer, made personally to himself, and which he (Dr. Haughton) drew up on that occasion. Earl Spencer informed him that he (the Viceroy) was completely satisfied by the statements in it; but the report was not then made public. There was no reason now that it should not be made public, and why Mr. Minchin should not have the full benefit of the justification contained in it, which he (Dr. Haughton) believed he then made for him. On the 20th of July, 1865, the last public execution took place in the county of Dublin; it was that of Patrick Kilkenny, at Kilmainham. He (Dr. Haughton) was present at that execution, by permission of the late Lord Mayo, and for reasons that were stated in the report, which he would presently read. It was not any morbid curiosity or any improper desire to assist at such scenes that induced him to be present, but a laudable scientific zeal in pursuit of knowledge. On that occasion he took no part in designing the fall of the drop; he was simply the hurler on the ditch watching what was done and recording it. The man's weight was 160 lbs., and he got what appeared to him (Dr. Haughton) the extraordinary drop of 14 feet 6 inches. He weighed the man, and he measured the drop with his own hands, so that there could be no doubt about those facts. He was assisted at the post-mortem examination, which they were permitted to make, by Dr. Arthur Wynne Foot. They found that the anterior articulating surfaces of the second vertebra were fractured near their posterior border, the fracture of the bone extending as far as the foramina for the vertebral arteries. The knot was occipital, and the soft tissues of the neck, including the trachea, œsophagus, and sterno-mastoid muscles, and the carotids and jugulars, were completely cut across except the skin. There was not the slightest abrasion or injury done to the skin. Death was instantaneous. He stood beside the man, whose thumbs crossed rapidly the palms of his hands, and he seemed to be dead the moment he came to the bottom of the fall. On the 28th of July, 1870, Andrew Carr was hung. It was the first private execution in Dublin, and took place in Richmond Bridewell, and the responsibility of advising with regard to the mode of execution devolved upon Mr. Minchin, who was surgeon to the gaol. Mr. Minchin, finding that Carr was 158 lbs. in weight, and only two pounds lighter than Kilkenny, suggested that, in accordance with an established formula, the drop should be about 14 feet. He (Dr. Haughton) asserted unhesitatingly that, from the knowledge which existed at that time, Mr. Minchin was perfectly justified by humane considerations in recommending such a fall to be given. The result, however, was different. His head was cut off. There was a transverse fracture of the second vertebra, and displacement of the second vertebra from the third. The knot in this case was occipital, the same as in the case of Kilkenny. There was no difference, in fact, in these two cases, except in the rope. An inquiry was held very properly into this matter, and after the investigation was over, Earl Spencer requested that he (Dr. Haughton) should forward, through Mr. Lentaigne, Inspector of Prisons, a scientific report on the whole case. This he accordingly did, and the report he made was as follows:—

Trinity College, Dublin,
22nd December, 1870.

DEAR MR. LENTAIGNE,—In reply to your communication of 10th September, enclosing the evidence taken by yourself and Dr. Hatchell respecting the execution of Andrew Carr on the 28th July last, I wish to make the following observations, which possibly may be of some use to the authorities charged with the responsible duty of carrying out the extreme sentence of the law on some future occasion.

I was not consulted respecting the execution of Andrew Carr, nor was I present at it; and my knowledge of this

subject was acquired in the following way :—Having been engaged for years in collecting materials for a work on Animal Mechanics, and never having had an opportunity of examining the body of a man who had met with a sudden death, I asked and obtained leave from the authorities to make an examination of the body of Kilkenny, who was executed in 1865 at Kilmainham Gaol. My object in so doing was to obtain the exact weights of certain muscles in the living body, and thus to interpret the results I had obtained by weighing the muscles of those who had died from natural causes.

Having been present at the execution of Kilkenny, in pursuance of the above-named object, I availed myself of the opportunity to study the conditions of death by hanging.

Mr. Price, Governor of co. Dublin Gaol, has stated in his evidence that the direction given at the time of Kilkenny's execution was that he should get a drop of 9 feet. And Mr. Boyd, Governor of Richmond Gaol, has stated that Mr. Price remarked at the consultation the day before Carr's execution that 14 feet drop was too great, and would take off the man's head.

Mr. Price is no doubt correct in stating that he gave the order for a 9 feet drop in the case of Kilkenny ; but it is certain that Kilkenny got a much greater drop than 9 feet, for I measured with my own hands the interval from Kilkenny's feet when suspended to the level of the platform on which he previously stood, and found it to be 14 feet 6 inches. The difference between the drop ordered and the drop actually given probably arose from the executioner measuring the drop from feet to neck, and not from feet to feet, which would give a difference of 5 feet.

Dr. Hemphill's evidence shows that, in the execution of Burke, at Clonmel Gaol, a drop of 16 feet was given, measured from feet to feet.

So far, therefore, as previous experience could guide him, in my opinion, Mr. Minchin, Surgeon to Richmond Gaol, was quite justified on humane grounds in ordering a drop of 14 feet in the case of Andrew Carr, for his weight was comparable with that of Kilkenny and of Burke, (*a*) but care should have been taken to ascertain that the ropes used were of similar degrees of elasticity.

Mr. Rorke, J.P., has stated in his evidence that the rope which hanged Kilkenny was much more elastic than the rope which hanged Carr ; and it is well known that the shearing force of an elastic cord or rope is less than that of an inelastic or rigid rope. The elastic rope is like a cable coiled round a post, by means of which the way of a large ship may be safely stopped, provided we allow the coil to slip gradually ; while the rigid rope is like the same coil held tight, a process which will snap asunder even the strongest cable without producing much effect in stopping the way of the ship.

Mr. Price stated that at Kilkenny's execution the rope was stretched 2 feet by the fall.

Assuming this to be the case, I have calculated that the shock on the neck was applied as follows, through the 2 feet of stretching :—

Expansion.	Shock applied to Neck.
0—3 inches	40 ft. lbs.
3—6 ,, ...	120 ,,
6—9 ,, ...	200 ,,
9—12 ,, ...	280 ,,
12—15 ,, ...	360 ,,
15—18 ,, ...	440 ,,
18—21 ,, ...	520 ,,
21—24 ,, ...	600 ,,
	2560 ft. lbs.

Thus the entire shock of 2560 ft. lbs., instead of being applied suddenly, was brought to bear on the neck by a gradually increasing strain—a process much less likely to destroy the structure of the tissues of the neck.

I may add that, in point of fact, in the case of Kilkenny the injury done to the bones of the neck was limited to the gentle fracture of the transverse processes of the 2nd cervical vertebra, and that the skin was not injured in the least degree.

In conclusion, I would observe that the long drop has been used in Ireland from time immemorial, with the humane object of shortening the sufferings of the criminal, and the records of Irish executions show that the drop has ranged from 9 feet to 16 feet.

In English executions the drop ranges from 2 to 3 feet only ; and I am informed by Mr. Gibson, Surgeon to Newgate, that during his long experience he has known but one case in which death was rapid (case of Müller, executed for murder of Mr. Briggs on Metropolitan Railway).

Taking all the foregoing circumstances into account, I am fully of opinion that Mr. Minchin was justified in making practical use of the old Stoic maxim for the alleviation of pain mentioned by Cicero—

"Si longus, levis ; si gravis, brevis."

I am, dear Mr. Lentaigne,

Yours very faithfully,

SAMUEL HAUGHTON, Clk. M.D.,

Fellow of Trinity College, Dublin.

John Lentaigne, Esq., J.P.,

Office of Inspectors.

He took for granted in that report the statement of the actual amount of the spring of the rope, and he had no doubt of the correctness of it ; but he thought it right to make experiments on the ropes themselves. For this purpose he got possession of the rope that hanged Carr, the rope that hanged Montgomery, and the rope that hanged Kilkenny. He got those ropes on the condition that he might use them in his experiments, but that he must return them whole. He did not think it necessary to bring the ropes to the meeting, as no person in the room, unless he were a ropemaker, would see much difference in them. The results of the experiments were recorded at the time with great care. They were made under the direction of Dr. Downing, Professor of Engineering. Having fastened one end of the rope firmly to the end of a horizontal table, it was passed across the table by means of pulleys over a wheel at the other extremity, and terminating with a scale pan, which could be loaded with varying weights. Two needles were fastened at points of the rope twelve feet apart, and under these needles graduated cards fastened to the table. When the scale pan was loaded with increasing weights the ropes stretched, and the needles both moved forward through an amount measured on the graduated cards. The difference in the motion of the needles gave, then, the amount of stretch of the twelve feet of rope for the weight used. Kilkenny's and Carr's ropes were what are technically called 2-inch ropes. The measurement of the rope was by circumference, and not by diameter. Montgomery's was a 3-inch rope, and much more clumsy than the others. The stretching of the ropes was respectively as follows :—Of Kilkenny's rope, 1-2107 ; the rope that took Carr's head off, 1-8144 ; and Montgomery's rope, 1-10464. The stretching power of Carr's rope was about one-fourth that of Kilkenny's. In other words, when they placed a weight upon the scale pan to stretch Kilkenny's rope, to move it from 5 to 6 inches—or any given number they liked—it took four times as much weight in the scale-pan to stretch the rope that hanged Carr. This was explained by Mr. Rorke, a manufacturer of ropes, on a principle of stretching ropes, which he (Dr. Haughton) did not understand, not being a ropemaker. It would be shown by a series of calculations with which he would not trouble the meeting, that when a rope is stretched by a weight to a certain point it springs below that and comes back. That was called technically the spring of the rope. It was observed, and he believed correctly, by Mr. Boyd and Mr. Price, to be two feet in the case of Kilkenny. The spring of the rope was proportionate to the square root of its elasticity. The spring of the rope that hung Carr was only half the spring of the rope that hung Kilkenny, so that all he had written in his report to Earl Spencer about the subdivision of the strain over the two feet took place in Carr's case, over one foot. They could easily understand how much more efficacious that was in destroying the neck. If the same rope that hanged Kilkenny had been used in Carr's case his head would have remained on, because the strain would have put on a spring of two feet instead of one. These facts were

(*a*) Weight of Burke, 168 lbs.; weight of Kilkenny, 160 lbs.; weight of Carr, 158 lbs.

not known, as he had said before, at the time Carr's execution was ordered; therefore no blame could attach to the persons who were responsible for it. He now turned to the practical conclusion that the ropes should be tested before an execution, and that if the rope be found very stiff and inelastic, then a shorter drop should be given than in the case of a longer rope. In both of the cases the knot was occipital. Now he came to a case which called attention not so much to the rope as to the position of the knot, and which would be well worthy of attention if they were called upon to superintend such a distressing thing as an execution. Montgomery was hanged on the 26th of August, 1873, in Omagh Gaol. It was a private execution, and he (Dr. Haughton) was indebted—so also were the readers of the MEDICAL PRESS—to Dr. Murray, of Trinity College, for the only report made of this execution. It would be in the recollection of those who might have had an interest in that celebrated murderer that the whole county Tyrone was visited on the morning of the 26th of August by the most terrific thunderstorm that ever was remembered in that part of the country. It produced the effect of washing the soap off the rope which had been hung from the gallows during the night, and the executioner, on coming in the morning to adjust the rope round Montgomery's neck, found to his great astonishment that the rope would not run freely. The governor of the gaol called upon the executioner to be quick, and in the hurry the knot was put on clumsily, and accidentally it slipped round under Montgomery's chin and nearly slipped off his face. Montgomery was 180 lbs. in weight, and he got a drop of seven feet. The knot was sub-mental, not occipital, and the shock came directly on the vertebræ—on the back of the neck. He was killed almost instantaneously. Though his death was rapid, he made two attempts at breathing, and twitched the right foot. It certainly was a rapid death. No post-mortem examination was allowed. There was an inspection by (the late) Dr. Thompson, of Omagh, who came to the conclusion that there was fracture of some of the cervical vertebræ—possibly the second, owing to the mobility of the neck; but he remarked that there was no compression of the windpipe or blood-vessels in front of the neck. Death had been caused in this clumsy execution in all probability, as Dr. Thompson had said, by the fracture of the spine. He (Dr. Haughton) was authorised in connection with this to quote a case which had been placed at his disposal by his friend Dr. Darby. It was the case of a poor gentlemen who many years ago resided in the co. Wicklow, and who was a lunatic. His wife and keeper lost sight of him for a short time, and he had time, it appeared, to retire into the garden. In searching for him the keeper went by a wrong passage into the garden, in consequence of which an interval of, it had been computed, two minutes had elapsed from the time he could have committed suicide to the time the keeper found him. The gentleman had committed suicide by hanging himself to an apple-tree. He (Dr. Haughton) was informed that this was a man who, though a lunatic, was fond of his personal appearance, and he carefully muffled up his chin with a silk handkerchief or muffler, then made a bit of rope tight under his chin, and dropped himself not more than two feet from one of the boughs of the apple-tree. He was hung intentionally, the same way as Montgomery was accidentally, by the chin, in order to save his appearance, and he (Dr. Haughton) was informed by Dr. Darby that there was no pressure of the rope on the vessels of the neck. There was no disfigurement of the face. In all probability, notwithstanding the short drop, death was not caused by suffocation or by any injury of that sort, but by injury to the spinal cord. These two cases showed the length of the drop which it might be desirable to give, and which, when the knot was occipital, might be considerably diminished if they contrived to make the knot in front. He was consulted in the spring of this year by the county engineer of Tipperary in connection with an execution which took place on the 9th April, 1875, at Clonmel. Some time before, an execution had taken place which shocked the whole country, owing to its having been carried out so awkwardly and clumsily that the unfortunate man fell on to the ground and struggled for forty minutes. The circumstance aroused the feelings of every person of education, as well as those of the lower classes, and a strong feeling prevailed that such barbarity ought not to be allowed. He (Dr. Haughton) was consulted by the county engineer, who was entrusted with the erection of the scaffold, and was asked for the best advice he could give. The man was executed by Marwood (who was the successor of Calcraft—an advocate of the short drop), and the horrors of the short drop were now at an end. Marwood, who favoured the long drop, had revived what there was ample evidence in Irish literature to show was the ancient practice in this country—the knot placed under the butt of the ear. Anyone acquainted with Irish literature would recollect Dean Burrowes' song, "The night before Larry was stretched," which afforded evidence of this fact. An eye-witness had informed him (Dr. Haughton) that in the execution of Russell at Clonmel the knot was tied under the left ear. The drop was seven feet, and there was no motion save that "he twisted bodily quarter way round towards his right hand." On the 26th April, 1875, Marwood executed a labourer, named Hole, at Bristol. His weight was 210 lbs., and the drop 5 feet, with the knot placed under the butt of the jaw. Baker and Cooper were executed by Marwood at Liverpool in July of the present year, and the drop was by measurement 6 feet 3 inches. Some persons in the habit of attending executions at Liverpool, when they saw the ropes dangling before the culprits were brought out, made an exclamation to the effect that the ropes were "three times as long as old Calcraft used." Mr. Gibson had informed him (Dr. Haughton) that Calcraft's favourite drop was 2 feet. Mr. Gibson had often seen people struggling for twenty minutes and upwards. Calcraft could not be induced to adopt a longer drop, and, like most old people, was thoroughly conservative in his notions. He (Dr. Haughton) would mention, in conclusion, two cases that had been supplied to him by Dr. King, which, if anything were wanted to confirm the perfect safety of giving a drop much longer than 6 or 7 feet, without much, if any, elasticity of rope, supplied corroborative testimony. They were not, of course, in a case like Carr's, to recommend a 14-feet drop unless the rope was very elastic. With a very elastic rope, if sufficiently long, attached to an elastic beam, they might from the top of St. Paul's dip a man fastened to that rope into the Thames and bring him up again without his head coming off, if they took time. For all practical purposes a 10-feet drop was, in his opinion, enough. On the 27th of August, 1853, Hurley was executed at Galway. His weight was 147 lbs., and the drop was 7½ feet. There was no dislocation or fracture of the vertebral column, or injury of the ligaments of the spinal cord. Lydon was also executed at Galway, on the 11th May, 1858. They gave him a drop of 11 feet, his weight being 133 lbs. These cases showed that the old Irish practice was a drop of 10 or 11 feet. The anatomical injury in Lydon's case was much slighter than Dr. Foot and himself found in the case of Kilkenny, where the drop was 14 feet. That portion of the anterior common ligament of the spine which passes from the body of the second to that of the third cervical vertebra was ruptured, so that the left halves of the bodies of both vertebræ were separated from each other by an interval of ⅛ inch, but there was no displacement. It was quite certain that the anatomical injury of a fall of 10 or 11 feet, with care in selecting the quality of the rope, was not very serious. Death was very rapid, and possibly as a practical rule for those who would not like to take the trouble to examine how many feet more you could go with this rope, and how many more with that, it would be well to adopt as a formula a drop of 10 feet, and to place the knot under the chin. This would in all cases give a speedy death, and save the surgeon from the unpleasant consequences of an accident.

DISCUSSION.

MR. TUFNELL.—What form of knot would you suggest?

The Rev. Dr. HAUGHTON said that Marwood's knot was always the running noose, and he used a two-inch rope. The old-fashioned hangman's knot was not now in vogue. It did not run so quickly as the other, and the pressure did not come on the neck so quickly. Montgomery was, however, hung with the hangman's knot.

Mr. BUTCHER said the Society might feel indebted to Dr. Haughton for coming forward with his observations, which were of extreme value, when it was remembered that it was the duty of any surgeon to contrive to alleviate pain and to shorten the sufferings of such a mode of death. The point struck him forcibly, and it was one that had not been cleared up by dissection, but which from an accident he had seen occur in reference to this manner of death, induced him strongly to suggest that the rope should be placed in a particular position. Mr. Butcher then related two remarkable instances of death, in one of which a horse run rapidly into a stable, striking the forehead of the rider against the top of the stable door. In the other case a horse ran away with a carriage, and in rushing under a bridge the head of the driver came in contact with it. On an examination of both those cases the transverse ligament of the atlas was torn across, and the odontoid process of the axis was thrown backwards on to the spinal cord, crushing it and causing instantaneous death. He did not think a person could fall many feet without the transverse ligament being ruptured. The knot should go under the chin, and the man's weight being thrown down, forced the ligament, the odontoid process was then thrown backward into the spinal column, and death immediately followed. He spoke now from those accidents to which he had referred, and which he had an opportunity of examining afterwards.

The PRESIDENT asked Dr. Haughton whether he had met with a case. He (Mr. Hamilton) thought it was recorded in Beck's "Medical Jurisprudence," in which a comparison was instituted between two executions in which one man was said to have given the body a peculiar twist, and that was supposed instantaneously to have had the effect of rupturing the neck ligaments.

Dr. HAUGHTON said he was acquainted with the cases.

Dr. HENRY KENNEDY said he would wish to make one remark, and that was as to the difference of strength of the materials of the neck, if he might so express it. He need not tell anyone who had been in the habit of examining the human body that great differences existed as to the development of the muscles, ligaments, bones, and processes, and frequently enough to entitle them to say that there was a great difference in the strength of one man's neck as compared with that of another. He thought that would have an important bearing on the subject which Professor Haughton had brought forward. He (Dr. Kennedy) had seen great differences, and all anatomists would bear him out in the fact that the differences of strength in the neck—the differences in the strength of the materials of the neck—of the human subject were considerable, so much so as to lead necessarily to a great difference in the strain, no matter how the rope or knot was applied.

Mr. TUFNELL said that Dr. Haughton had spoken of the position of a medical man in the public service having possibly to attend an execution. Such had been his (Mr. Tufnell's) lot. He had had to attend the execution of a man, but in that case they had to hang him with a cotton rope as thick as his wrist. In that case the man died by strangulation, and suffered a great deal. He thought in that case it would have been desirable to have had the knot placed anteriorly, so as to have chucked the head backwards. He had seen the case of a boy carrying a basket on his head with the handle under his chin, and another boy came behind him and gave him a pat on the back. The result was that the head was thrown back and he was killed instantly. In the case of execution to which he had referred, it was at first proposed to run the man up to the yard-arm.

Mr. B. WILLS RICHARDSON said he thought the cases alluded to by the President had been originally described by Louis, the great French surgeon, who had investigated the subject of suicidal hanging, and who said that it was remarkable that all the people hanged in Paris—this was of course before the time of the revival of the guillotine—died of apnœa. In the cases of all those hanged in Lyons the executioner gave them a twist when he was shoving them off the ladder, and thus it was that with that short drop their necks were broken. These cases were recorded by Louis, and Boyer also mentioned them.

Dr. M'SWINEY said that he had hoped that Professor Haughton would have been able to lay down some strict scientific rules whereby they could accurately determine in any given instance the length and diameter of the rope to be used in relation to the fall from the drop and weight of the criminal. It was perfectly clear that three circumstances had to be taken into account in an execution—the length of the fall, the diameter and circumference of the rope, and its elasticity. Dr. Haughton, with his usual ability, had made that perfectly clear to the meeting, but it appeared to him (Dr. M'Swiney) that Dr. Haughton's conclusions were not as satisfactory as his opening statements. He did not furnish them with any fixed ratio or proportion whereby they would be advised in any given instance as to the circumference of the rope, the amount of elasticity (as determined by his own experiments), having reference to the weight of the individual and the length of the fall. Anyone who had investigated the question of executions knew that there were the greatest differences (as yet unexplained) in the amount of injury inflicted upon the criminal surrounding the question. Every variety of injury, starting from zero up to such an extreme instance as the decapitation of Carr, had been recorded after examinations made by competent persons of the bodies of those who had been executed—muscles, vessels, nerves, or skin either entirely divided or only partially injured—or even no appearance of injury at all. The ropes had varied in size, and the situation of the knot had been one time in front, at one time behind, and at another time at the side—according to the idea of the executioner; but no fixed principle had been laid down for the determination of what the proper adjustment on those occasions should be. He confessed that he had hoped that that would have been the upshot of the learned professor's paper, but he (Dr. M'Swiney) failed to perceive that that was so. It was obvious that Professor Haughton's investigations had advanced the subject greatly, but he (Dr. M'Swiney) would venture to say that there remained further investigation and inquiry before they could guarantee that no such accident as that which shocked everybody on the occasion of the decapitation of Carr would take place. The form of death was stated by those authorities in medical literature to be dependent on the situation of the knot. Thus, when the knot was in front it was laid down as a fact that often from the rope slipping too high up the death was from apnœa. When the knot was posterior, there was, when the fall was considerable, a violent injury inflicted on the spinal cord, and death was usually instantaneous, either from the injury inflicted upon the cord or—what was most commonly the case—from fracture or displacement of the vertebræ. When the knot was situated at the side, pressure on the nerves in that situation, as well as on the carotid arteries and other blood-vessels produced the fatal result, which resembled death by apoplexy. Post-mortem examinations had also clearly proved that death sometimes occurred from asthenia in these cases—sometimes in a form which seemed analogous to syncope. In fact, great mystery still surrounded the whole question, and the appearance presented *post mortem* varied infinitely. From the great amount of contradiction in the statements made by different persons in different countries it was obvious that the difficulty of arriving at a correct knowledge was very great. He did not think that the learned professor had as yet supplied them with a formula whereby they might be enabled to secure in every instance the immediate or speedy death of the criminal without such a disaster as occurred in the case of Carr.

Dr. DARBY said that, with regard to the case in which Dr. Haughton had been kind enough to mention his name, he might mention that the rope used on that occasion was what was commonly described as a sash-line, and very small indeed. It was imbedded deeply into the skin at the back of the neck. There was no congestion of the face or deformity of any kind.

Dr. JACOB said he thought it could hardly be complained of Professor Haughton that he had not laid down a definite instruction as to the course to be adopted because, while he had the other data and had shown them to the Society in a very complete way, he had admitted that he had not the datum which rested on the elasticity of the rope and the length of fall, and as it was an element or factor in the result which largely entered into the calculation, of course it was impossible for Professor Haughton to do more than indicate the drop which ought to be adopted. What he (Dr. Jacob) had hoped to hear was the best position for the knot in certain cases, and he would think that would turn in great measure on mechanical prin-

ciples, on the application of the rope, and on the strength or weakness of the ligaments of the vertebral column, and the structures of the neck viewed from their various aspects. With regard to what Dr. M'Swiney had said, that when the knot was placed in front death must take place from apnœa, he (Dr. Jacob) thought he must dissent from him. At the time Montgomery was executed it struck him (Dr. Jacob) at once that the mistake which the executioner had made in the hurry of manipulation had been the means of effecting a more theoretically complete execution than that which had been provided for previously, because in placing the knot under the man's chin he removed the point of suspension to a point much more nearly at right angles with the spine than the sub-aural or occipital position would give.

Dr. HAUGHTON: The executioner placed the knot on the occiput; chance put it under the chin. It was a pure accident, and therefore the executioner deserved no credit for it.

Dr. JACOB, in continuation, said he was not anxious to obtain credit for the executioner in the matter. The placing of the knot at a given distance from the point where the force is applied—the distance from the chin to the occiput—must necessarily throw a more or less perpendicular strain on the vertebral column, which was desirable. As to the application of the strain or compression to the larynx, trachea, or any of the soft parts of the neck, he took it to be regarded in our present light as a bungled execution where such occurred. He thought they must agree with Dr. Haughton that the old system of the knot at the occiput with an angular space immediately covering the back of the neck was theoretically and practically bad. The only question to his mind on which there remained doubt was the application of force under the chin, or the application of force under the butt of the ear, which Professor Haughton seemed to eulogise as the most skilful means of execution of the present day. Which of those were to be preferentially adopted? He should say that the first should be obviously the best to produce fracture of the transverse ligament as a matter of mechanical application, and it was for anatomists to say whether or not they could fix a point of the spinal cord where force in a given direction might better be applied. He thought that point of Professor Haughton's was worthy of attention, and he trusted some anatomists would be induced to state their views on the subject.

Mr. PEARSALL said that as strong confirmation of what Professor Haughton had said with reference to a considerable fall being necessary, any one who had read the details of executions recorded in the *Newgate Calendar* would remember that the culprits were launched from a cart, which must have left the drop a very short one, and nearly always the narrative wound up by stating that the man suffered a great deal.

The Rev. Professor HAUGHTON, in reply, said that Dr. M'Swiney had said that the commencement of the paper was quite clear and the end obscure. He (Dr. Haughton) regretted that he failed to convey his meaning, but it was probably owing to the fact that he was really anxious to save the time of the meeting. Dr. Jacob had quite misunderstood him (Professor Haughton) in saying that he preferred the knot under the ear to the chin. It was quite the contrary, and he said, though there was the classical evidence of Dean Burrowes' song to show that such was the practice of former times, that Marwood now used the sub-aural knot, and that was enormously beyond Calcraft's practice. He (Dr. Haughton) dissented from that, and when he was consulted on the subject of the Clonmel case he proposed that a short iron bar about an inch in diameter and 6 inches long should be placed under the chin and the knot fastened into that. The chin would rest on the bar of iron. The knot should be fastened around this bar, brought round the back of the neck and wove through a loop at the opposite end of the bar. By this means the rope would be in direct opposition with the spine, and death would be produced in the most rapid possible method—in a way that he considered was the most rapid mode of producing it, and which he was glad to find men of such great experience as Mr. Butcher and Mr. Tufnell confirming. He would beg the meeting to remember that he was helpless in this matter, that his suggestions, however well made, were very slow of bearing fruit, because in this conservative country there was no more conservative branch of the executive than that controlling the execution of criminals. He had shown in his published book that Calcraft, when he hanged the men with 1½ feet, and scarcely ever 2 feet of a drop, was the lineal descendant and representative of a state of things utterly different from modern civilisation. The old sentence was that "you shall be taken from the place where you now stand and hanged by the neck until you be dead." But that did not mean dead as we mean—it meant merely insensible. The man was to be hanged up gently for ten minutes and then placed before a large fire. The executioner was then to disembowel him and throw the entrails on the fire. Hanging was not intended in those times to kill the criminal. He was merely anæsthetised, then drawn and quartered, and he (Dr. Haughton) believed the old sentence had been carried out literally according to the custom of past generations, and that Calcraft was only doing what was done in the days of the Plantagenets. He (Dr. Haughton) had no doubt it would in those days be regarded as a most terrible innovation to carry out what was done at the present time. They must remember, however, how helpless a man was who connected himself with such a conservative institution. Mr. Gibson, who had spent fourteen or fifteen years of his life in trying to improve the executions at Newgate Prison, was so situated since private executions became the law, that it was impossible to give more than a 2-feet drop without showing the whole exhibition to the general public outside. For a long time Mr. Gibson suggested to Calcraft, and endeavoured to persuade the Governor of Newgate, to allow a large cellar in the prison yard to be opened, so as to allow the culprit to drop down into it, after the Irish fashion. Well, Mr. Gibson had to wait until Calcraft resigned before his request could be complied with. Now they had Marwood in place of Calcraft, and Marwood gave a drop of 6 or 7 feet, and hanged with the sub-aural knot. That was a great improvement on the occipital knot and the 2-feet drop. Death was effected by the submental knot in the very way that rabbits were killed when struck on the back of the neck. Dr. M'Swiney had complained very seriously of the want of anatomical details in connection with these executions. Well, in one of the two cases he (Dr. Haughton) had recorded—that of Montgomery's accidental death by the knot being under the chin—owing to a compliance with the expressed desire of the culprit that his body should not be cut up, no post-mortem examination was made. Dr. Thompson had to be content with a mere handling of the neck. With regard to what the President had said about the twist, he (Dr. Haughton) inquired many years ago carefully into that, and he could find no anatomical evidence such as the President suggested. The only accurate records of dissected bodies recording injuries to the spine were those he (Dr. Haughton) had published himself, and the two cases of Dr. King. Dr. M'Swiney complained that he (Dr. Haughton) gave no rules. It was impossible to give a rule. He had not had the means of experience. If he offered his advice it might be refused, such was the obstinate conservatism of the executive in this country. And such was the obstinate conservatism of the Newgate authorities that it took years upon years to establish the small reform he had alluded to. There were three elements to be considered with reference to the subject of his communication. The first was the weight of the man; the second, the nature of the rope; and the third, the amount of the fall; and until some light was thrown on the question by anatomists dissecting men who had been hanged, they would know no more than at present. He had gone a great step towards improvement, and he felt he had no apology to offer the Society for having brought the subject before them. Some one or two of his friends—more careful of his character than he was himself—had said it was undignified of an anatomist and a clergyman to deal with such a nasty subject. He was indifferent about his character; it was quite able to stand alone and bear the attack of an open enemy, as well as the secret backbite of a friend. Dr. Kennedy had said that necks had different strengths. He (Dr. Haughton) did not see how that remark applied. The degree of force applied by the variation of the elasticity of the rope was unfortunately greater than the variation in the strength of necks could be supposed to be. As nearly as possible the strain on the neck was in the proportion of five to three. That was an enormous difference. That difference showed them that the element of the elasticity of the rope was one to be carefully guarded against. He would sum up by saying that generally a moderately elastic rope did not cut like a rope like a ship's cable. If they had a moderately elastic rope with a drop of 10 feet he thought they would be safe.

The Society then adjourned.

WEDNESDAY, JANUARY 5, 1876.

THE ABOLITION OF PAIN.

The *Daily Telegraph* appears to be sorely distressed to think that medical science has not been able to place in the hands of the public a drug which would not only be a panacea for all kinds of pain, but which any one could use as he liked without running any risk of doing himself any harm. This is certainly a very modest request, and we wonder what will be the next thing that the *Daily Telegraph* will demand of the profession. To supply the public with a nostrum which they could send for to take away their pains as surely and as safely as they can send for a glass of ale to quench their thirst is certainly a novel idea, but a little behind the times. We thought that the age of the "Philosopher's Stone," of the "Universal Solvent," and the "Elixir Vitæ" had passed away. We are sorry to see we are mistaken. We are sorry to see that the credulity and scientific ignorance which gave rise to a belief in those wonderful discoveries are not yet extinct, and that a leading journalist of the nineteenth century believes in the possibility of finding an universal nostrum as potent and far more valuable than any that have hitherto entered the imagination of man. We should not perhaps have taken any notice of the little article in which we are so seriously called to account, thinking it might very probably be written by one whose physical torments had warped his judgment and had soured his temper; but some months ago our censor made similar complaints respecting the shortcomings of medicine, and now that he has returned to the attack, we cannot resist the temptation of thanking him for his kind suggestions, as well as for the high opinions he must have of our magnanimity, and of our readiness at all times to sacrifice our own interests to those of the public. Our facetious contemporary *Punch* has, while contemplating the health in store for the inhabitants of our future "Hygeiopolis," represented the poor doctor going about begging for halfpence; and if the promised land is one where not only bad drains, but bad pains, will be almost unknown we think that *Punch's* idea is more than a joke, and that at our expense his dream will be too surely realised.

But, to be more serious, we regret to see that so influential a paper as the *Daily Telegraph* has, by its remarks, rather encouraged than otherwise their invalid readers to indulge in a habit which never will be practised with impunity. Those remarks were made with reference to the recent death of Lady Chesterfield and of Mrs. Childers—the former having taken an over-dose of laudanum, the latter of chloroform. We are sarcastically asked, "Can medical science, which, we are told in numerous annual lectures and at scientific congresses, is always active and always gaining fresh triumphs—can it do no more than tell people, maddened with pain, that they run a serious risk in relieving their agonies by the only means available?" We are then told that since Dr. Simpson's invention of chloroform we seem to have stood still, that we have not discovered "the mode of rendering it safe in *uninstructed hands*" (the italics are our own); or, what is worse, "discovered any new anodyne a few extra drops of which would do no harm;" that some such revelation of science is what we want, rather than barren lectures on caution; and, finally, we are asked what good has come from the numerous experiments of the last thirty years? what vivisection has to say for itself in the matter? and so forth. The absurdity of all this rhodomontade is patent enough, and we hope too much so for the public to take any notice of it. It was, moreover, rather an unfortunate subject on which to call us to account, considering that if there is one thing more than another for which medical science has within "the last thirty years" reason to be proud, and humanity for ever grateful, it is the discovery of chloroform, ether, nitrous oxide gas, and other anæsthetics. But to expect that these or any other potent agents can be made safe in "uninstructed hands" is the height of folly. We may ask of our critics if they know any potent agent, from a drug to a torpedo, that is safe in uninstructed hands? And, again, it requires very little consideration to see that such "a revelation of science" as the *Daily Telegraph* looks forward to is an impossibility. The abolition of pain must always depend either upon the removal of the cause, or upon dulling or otherwise affecting the sensibility of the nervous system. It is evident that the removal of the cause must, where possible, rest entirely upon the skill of professional men. And when this is impossible, and powerful anodynes or other agents have to be resorted to as palliatives, it is from the nature and functions of the nervous system equally evident that the more certain and powerful the narcotic, the more will be the risk incurred by using it incautiously. The brain and nervous system are only proof against a limited dose of narcotism, and if this is exceeded, a fatal result ensues. Now this limit, or toleration of narcotics, varies, as everyone knows, according to the constitution and idiosyncrasy of the individual; and it is not always possible for a medical man, much less for the patient himself, to be certain that a large dose, given in a desperate case, will not be attended by serious consequences. There are pains so excruciating that the quantity or strength of drugs which would be required to completely remove them would far exceed that which would, in some individuals, be sufficient to destroy life. Therefore, however successful

we may be in discovering, at some future time, drugs that are more certain and convenient than those now in use, they never will be such as can be safely left to the indiscriminate use of the public.

THE MEDICAL COMMISSIONERSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

THE resignation by Dr. John MacDonnell of his office as Medical Commissioner has, as we anticipated, been presented at the end of the year, and great interest is excited within the profession in Ireland, and especially amongst Poor-law medical officers, as to the succession to his important and lucrative office. The candidates, as we have already stated, are Dr. Rawdon Macnamara, representative of the College of Surgeons in the Medical Council; Dr. Malachi Burke, Medical Superintendent of Registration; and Dr. Croker King, one of the Inspectors under the Board; and we trust their relative merits will be well considered, and that no political ear-wiggery or personal intriguing will be allowed to exercise an influence against the selection of the best man for the service. Dr. Macnamara is unanimously admitted by the profession to possess all that should make him suitable for such preferment. He has proved his administrative activity and competency in circumstances similar to those which the office would present. He has had experience in the Poor-law Medical Service, and is thoroughly acquainted with its working, and is known to combine the *fortiter* which is wanted to deal with contumacious officers and the *suaviter* necessary for diplomatic dealings, at the same time that he enjoys the rank in the profession which entitles him to consideration. Dr. Croker King has been for some years associated with the Poor-law Medical Service in Ireland, and is known to be a man of talent, and thoroughly conversant with the subject. We appreciate fully the propriety of the principle of promotion within the service, though we cannot regard that consideration as pre-eminent to all others in the selection of a successor to Dr. MacDonnell. Dr. Malachi Burke having been for some years the Medical Superintendent of Registration, is, no doubt, a good statistician, and possesses a certain knowledge of the Poor-law system; but these qualifications are hardly those which may be looked for in the occupant of so important a post.

The policy of abolition, against which we have written some weeks since, is, we hear, rather in the shade, in consequence of the simultaneous expression of condemnation which it evoked. In spite of what may be said to the contrary, we have reason to know that it was seriously entertained, is not yet abandoned, and would possibly be revived if the profession were to relax their opposing vigilance; and it is not at all unlikely that the office may be kept in abeyance until late in the session of Parliament, with a view to possible further legislation, which may deal with the amendment of the Lunacy and Sanitary Systems in Ireland.

The retirement of Dr. John MacDonnell requires from us more than a mere record. A reference to past volumes of the MEDICAL PRESS is sufficient to remind us that we have many times contested with the Medical Department of the Irish Poor-law Commission the policy of its acts, and have been unsparing in our disapproval whenever we found medical men harshly or despotically dealt with, or when any step was contemplated (such as the Central Union Drug Store job) which we thought would be prejudicial to the service. Having thus candidly differed from the Medical Department of the Poor-law Commission upon occasional instances of what we considered injustice or imprudence, we have the less hesitation in saying that Dr. John MacDonnell leaves the service with the well-deserved regard of the Poor-law medical officers as a body. Many of them, in adverse circumstances, have found him ready to yield as far as the real good of the service permitted, and we would much mistake his kindly nature if we debited him alone with occasional arbitrary acts from which individuals have suffered. Of recent years the Medical Department of the Local Government Service has been unexceptionable in its management, only needing more activity to make it as perfect as a public administration can be, and we give Dr. MacDonnell the credit which we believe he has earned, of having tempered the slap-dash despotic system upon which affairs were formerly transacted.

We do most earnestly trust that—if for only this once—a good appointment will be made to the Medical Commissionership; but our experience of the exercise of Irish medical patronage hardly permits us to hope that the merit of a candidate or the good of the service will have much to say to the selection. If the canvass for this office be like that of similar places in Ireland, we know well how the wires are being pulled at Dublin Castle—how every county in Ireland is being ransacked for personal influences—how every M.P. is being whipped in—how every out-of-the-way cousinship is being worked to advantage—and how little is thought of the irremediable damage to a great service which would result from the installation of Incompetency at the head of it. Will we ever light on a Government which will shut its ears to the importunities of hangers-on, and appoint the public servant for no other reason than that "he knows what he has to do, and does it?"

THE SCIENTIFIC EXECUTION OF THE DEATH PENALTY.

THE breathless yet painful popular interest which has been excited by the infliction of a well-deserved death penalty on the murderer Wainwright will cause the profession to read with increased attention and interest the contribution to the discussion of the scientific points in such a proceeding which we publish from the pen of Professor Haughton, of the University of Dublin, in our issue of to-day. The learned professor has been moved to devote his attention to a subject which some may think beneath the level of his scientific reputation, not only by the bearing of the study of physical force applied to the human body upon his well-known researches in Animal Mechanics, but from a feeling that humanity required that he should not hesitate to do all in his power to alleviate suffering in cases of legally inflicted death.

This is a philanthrophic purpose, falling properly within the province of the reverend author, and he gives in his paper good reason for his feeling in the matter when

he quotes the statement of Mr. Gibson, the Surgeon of Newgate, that, under Calcraft's *régime*, he has frequently seen the victim struggle for more than twenty minutes before becoming inanimate. We need not follow Professor Haughton through the course of his investigations, or his reasons for his conclusions. He comes to the following firm deductions from his facts :—

1. That the old system of taking the convict's life by suffocation is inhumanly painful, unnecessarily prolonged, and revolting to the spectators whose duty it is to be present.

2. That the object of an effective execution by suspension should be the immediate rupture of the spinal column by the fall.

3. That the use of a "long drop" (which by habit has become known as the Irish method), is not only much preferable from a humanitarian point of view, but is the only method by which the desired object can be effectively attained.

4. That the short fall and the position of the knot employed for so many years by Calcraft are barbarisms which should cease to be permitted.

5. That the fracture of the spinal column can best be instantaneously effected by placing the knot under the chin and allowing a fall of at least ten feet.

6. That in the carrying out of a capital sentence care should be exercised in the selection of a suitable rope.

In the execution of Henry Wainwright, it would seem, from the published accounts that these principles were adopted by Marwood, the executioner, and with perfect success, and that the instantaneous rupture of the spine resulted from placing the knot under the culprit's chin—a position which was unintentional in Montgomery's case, but was purposely adopted in Wainwright's. Professor Haughton deserves credit, not only for his devotion of himself to this matter, but for the courage which he has displayed in publicly associating himself with an unpalatable subject and a painful subject of inquiry.

CHARITABLE APPEALS.

Foreigners, and those persons quite unacquainted with the sociology of this vast metropolis, must look with perfect astonishment on the long list of charitable appeals that crowd the columns of the daily press. Appeals for help cut a pretty periodical figure, and must appear unaccountably strange to those who are accustomed to see the management of charity in the hands of the State. In this country every conceivable form of poverty and suffering finds its disinterested (!) advocate ready to do battle in its behalf, and fight its way to the large-hearted amongst the human race. How much, or rather how little, of the actual proceeds which these appeals extract from the pockets of the benevolent go towards relieving the poor and in support of the afflicted is quite another matter, and would be difficult to predict—indeed, it is known that by far the larger portion never reaches the classes for whom it has been subscribed.

The greater part of the charity-monger's work is unnecessary and uncalled for, and serves directly to give encouragement to the oft exposed and almost defunct begging-letter impostor, who finds a new way of plying his old trade, and in a far more profitable manner. Recent police exposures, set on foot by the Charity Organisation Society, show how easy it is to levy black-mail in the cause of charity (!), and on behalf of an imaginary "Society to Aid Widows and Orphans of the Fire Brigade," or a "Home of Hope" for "fallen young women, for whom little provision has been made," or any other mock institution with no other object in view than that of helping people to live who disdain to follow any honest calling. The daily newspapers have something to answer for in this business, since without let or hindrance their columns are open to all comers and all professed "*charitable appeals*," good, bad, and indifferent; and apparently editors think it no part of their duty to ascertain beforehand the merits or demerits of quasi-charities, and therefore it becomes very like the blind leading the blind, and whereby the benevolently-disposed fall into the ditch.

It would indeed be a hopeless task to make any attempt to show how far the majority of the miscalled charities that are thus permitted to appeal to the public fail in their duties to suffering humanity, or what return they make for the thousands annually lavished upon them; it is well enough known that only a very small number attempt to cover ground which has not been for many years far better occupied and covered, and in every way better adapted to serve the cause of the necessitous and really deserving poor. Subscribers to charities are not aware of the fact that two-thirds of donations given in answer to these appeals are absorbed by executive and promoters, and the other third goes towards relieving boards of guardians from performing duties thrown upon them by Acts of Parliament. The action of the press in other ways exerts a prejudicial and often demoralising influence upon society, since it shows schemers how easy and simple a thing it is to obtain money under false pretences, while it gives encouragement to what is looked upon by some people as a pardonable species of deception—that of putting forth appeals for help by a better class of charities, those entitled to append the word "Royal" before their other names, and whose wants, one would think, are amply supplied. We notice one glaring instance during the past week. The president and treasurer of the special institution is a Member of Parliament, and who acknowledged a fortnight ago the receipt of a legacy of £2000, nevertheless now grounds a strongly-worded appeal "to the charitably disposed" upon the "reputation of the surgical staff, which includes *two* well-known names (only imagine the blushes of the two eminent men, whose names are given, seeing themselves blazoned forth in the morning papers, while their colleagues, equally eminent, are left out in the cold—and all in the cause of charity!), which has caused the hospital to be universally known and its beneficent work appreciated to such an extent" that it is unequal to the task imposed upon it, and more beds are urgently needed, *although increased in number little more than twelve months ago.* Such a mode of puffing the reputation of certain favourite members of the staff and the merits of the institution is very reprehensible, indeed, is a most questionable and sensational way of bringing grist to the mill.

The *Times*—feeling some compunction of conscience in the matter and considerable difficulty in determining the rival claims of the various people who appeal to them,

and the worthy and unworthy among the competing hundreds—is apparently anxious to retrace its steps with a good grace. It acknowledges that by the present method it is hardly possible to separate the honest from the dishonest, and therefore offers a suggestion for a better method of collecting and distributing gifts among the several competitors. "Subscriptions," says the editor, "should be placed in the hands of a competent committee of gentlemen, who should undertake the task of distribution upon certain principles and under definite conditions." It would be, however, a most thankless task; but anything would be better than the present scramble, and by means of which the most undeserving and unscrupulous are certain to obtain the lion's share. It may be worth while to try a scheme of the kind. Doubtless a good many people would gladly welcome some guarantee that their money would be bestowed with a certain amount of thought and judgment in place of the present objectionable and haphazard method.

QUACK IMPOSTORS AND ILLEGAL PRACTICE.

We appear to be living in an age of impostors and humbugs, and at a time when the parasites and vampires among the community contrive to drive a lucrative and flourishing trade. Between spiritualism, fortune-tellers, necromancers, water doctors, and pill-mongers, the weak and foolish were never more thoroughly exposed to be cheated and victimised. One could almost fancy the country is passing through a retrograde movement, or that we are returning once more to the dark ages of three or four centuries ago. It is quite disheartening to think that while we are spending hundreds of thousands annually upon the education of the poor, all classes refuse to be enlightened upon medicinal matters, the treatment of disease and all that pertains to health and life. The water-doctor and necromancer of Banbury, therefore, still carry on a roaring trade, and contrive to delude the inhabitants of Long Compton and its neighbourhood that the arch-quack has the power to "exorcise evil spirits" and cure diseases by drinking his nasty concoction. A member of the medical profession who was examined as a witness on a recent trial for the murder of an old woman near eighty years of age deposed to the general prevalence throughout South Warwickshire in the supertitious belief in the powers of such monsters as "necromancers" to perform cures. Under a wicked and absurd delusion of the kind engendered by one of the fraternity, the poor half-witted creature James Heywood proceeded to the house of a decrepit old woman, Ann Tennant, for the purpose of "exorcising the evil spirit" which possessed him, by drawing the blood of his victim with a pitchfork, and thus destroying the power he was told she exercised over him. Can any tale be more horrible or degrading to human nature than this? The scoundrel of a "water-doctor," who was by far the worse of the two culprits in the foul deed, ought to have been placed in the dock by the side of Heywood and tried for the murder of this innocent and harmless old woman, who lost her life solely through his jugglery and agency. These water and herb doctors are the pests of society; nevertheless they are quietly permitted to ply their noxious calling, even to the destruction of mind and body of numbers of credulous persons. During the past week, however, there has been a show of putting down one of the fraternity practising in the town of Wolverhampton under the dignified title of Dr. Wardle, Agent to the Medical Reform Association, Boston, U.S. This man, it appears, was charged by the police with illegally using the title of Dr. and obstructing the highway by placing three caravans on an open space at the south end of the Waterloo Road. The proceedings were taken under the Medical Act, and the evidence showed that defendant sold his dangerous nostrums and distributed handbills in which his name appeared as Dr. Wardle, herbalist, &c. He produced an American diploma, which the magistrates termed a worthless document, fined the defendant, and ordered him to leave the town of Wolverhampton at once.

Notes on Current Topics.

The Lord Mayoralty of the City of Dublin.

On New Year's Day Dr. George B. Owens was installed, with all the usual pomp and circumstance, in the Lord Mayoralty of the City of Dublin, a position of honour of which any citizen might justly be proud. Dr. Owens has always enjoyed a wide-spread popularity amongst his professional brethren, and the reception which he received on his installation testifies that that popularity extends to all classes of his fellow-citizens. He was received with demonstration almost uproarious in its enthusiasm, and received a very warm eulogium from the various speakers on the occasion. On his return to the Mansion House he entertained his friends at a *déjeûner*, at which the President of the College of Surgeons, Dr. Banks, Mr. Porter, Surgeon to the Queen, Mr. Tufnell, late President of the College of Surgeons, and many other medical men were present. We are always gratified to see medical men in the front in public life, and congratulate Dr. Owens on his elevation to the civic chair.

Beastings.

Many a reader will recollect having been treated to a bowl of rich pink-coloured milk drawn from the cow immediately after calving. Their enjoyment of the recollection will be somewhat marred by the reading of an analyst's evidence in a recent sanitary prosecution at Woolwich. A milk dealer was summoned by the Local Board of Health for selling impure milk. Mr. Wigner, the analyst, said the milk, though very rich, was of a saffron colour, and he found *more than half the cream was blood*. He admitted that milk of a high colour and peculiar character was provided by nature for young calves, but said that in his opinion the cow which supplied this milk was suffering from foot and mouth disease. Defendant said it was usual to sell such milk, which was called "beastings," and was frequently used for making custards. Mr. Wigner replied that he was aware people cooked and ate it in the north of England, but it was as horrible as eating blood puddings. Mr. Balguy, the magistrate, said he had himself enjoyed many a meal of it; and Mr. Wigner replied that it might not be unhealthy when

cooked, but that it was sent as a purgative for the calf, and might, if given to an infant, produce vomiting, purging, and death.

Typhoid Fever at Croydon.

DR. BUCHANAN has been investigating the circumstances connected with the late outbreak of typhoid fever at Croydon, and to this end has specially directed his attention to the supposed causation of the disease from bad water.

Health of the Army.

ACCORDING to the Blue Book of the Army Medical Department just published, 8.28 per thousand of the troops serving at home died in 1873; 759 were taken into hospital, and 25 discharged as invalids. In foreign stations the admissions to hospital were 13.14 per thousand; there were 16.25 deaths, and 39.13 sent home, with 10.22 per thousand discharged as invalids. The average of the ten years preceding 1873 showed that 14.96 per thousand admissions took place, that the deaths were 24.96, the invalided 41.03, and the discharged 18.93. The health of our troops abroad is now much better than formerly, especially in China and India, and in Ceylon.

Hospital Nursing.

THE fearful tragedy lately enacted at the Norwich Hospital will, we trust, act as a warning to those entrusted with the management and care of hospitals. It will be seen, by what transpired at the inquest, that greater discrimination is needed on the part of those who undertake the responsibility of recommending patients for admission. The previous history of the patient, and especially if there be a suspicion of a maniacal tendency, should always be given, so that greater watchfulness may be exercised on the part of those left in charge. Good and careful nursing is a most essential element in the management of the sick, and in this particular the Norwich Hospital seems to have been greatly wanting. A most unaccountable laxity indeed was displayed in this department, for who would dream of a number of sick people being left without a proper night attendant? The best and most experienced nurse should be in charge of the patients during the night, as it is always during the dusky hours that paroxysms of delirium are invariably the most dangerous and difficult to manage. Deaths more frequently occur during the night-time, and on this account a trustworthy nurse should be in charge of the patients. It is grievous to think that, had an experienced person been on duty at Norwich, the terrible murder of these innocent boys might have been prevented.

Insufficiency of Asylum Accommodation in Ireland.

THE inspectors of lunatic asylums in Ireland record in their report just issued a complaint that the accommodation in Irish district asylums, not simply meaning the numbers they are made to contain, is much below requirements, as they have at present almost a thousand in them beyond their legitimate complement. Some are overcrowded by nearly a third, as those at Limerick, Armagh, and Londonderry—others less so. Taking a broad practical view of the subject, they consider that all these limited institutions should not only be restored to a normal condition by additions, but supplemented when necessary, so as to meet local requirements, thereby effecting a complete provision for probably 8,200 beds, the existing but imperfect one being restricted to 7,347.

Dublin Scientific Club.

THE Club which has been in existence for some years has been reorganised this winter. Its object is to afford its members and associates an opportunity of bringing forward in an informal and conversational manner subjects of interest connected with any department of scientific knowledge. A brief outline of the progress of one branch of science will in future be given by the Chairman, and form the introductory business of the evening, after which opportunity will be afforded to those present to make communications on scientific subjects.

The Club meets on the first Monday in each month of the session as below, in the theatre of the Royal Dublin Society. The members of the club dine together at the Shelbourne Hotel at six o'clock on the evening of each meeting.

During 1876 the meetings will be as follows:—
January 3, Professor Ball, F.R.S., Astronomy.
February 7, G. Johnstone Stoney Esq., F.R.S., Physics.
March 6, Professor Hull, F.R.S., Geology.
April 3, Professor Emerson Reynolds, Chemistry.
May 1, Professor W. R. M'Nab, M.D., Biology.
November 6, Professor W. F. Barrett, F.R.S.E., Physics.
December 4, A. MacDonnell, Esq., C.E., Engineering.

The Curative Efficiency of Irish Lunatic Asylums.

The actual recoveries in Irish lunatic asylums during the last twelvemonth amounted to 932, the discharged, improved, or convalescent to 244, and the deaths to 623. Calculated on admissions the cures reach 43·40 per cent., if on all resident 9·80; while cures and improvements combined are equal to 53·20 per cent. in the former, and 12·5 in the latter contingency. With regard to deaths, the mortality—particularly if the severity of a long winter and the liability of the insane to pulmonary affections be considered—may be regarded as particularly low, when not exceeding 6·80 per cent., the average in lunatic institutions generally being 8·40. Included within the deaths are 4 from suicide, and 5 succeeding on accidents in an aggregate daily population of 7,254 patients, of whom in the year 1,174 were received on magisterial warrants and by depositions as evincing dangerous tendencies.

Tobacco and Malingering.

IT was stated at one of the New York medical societies recently that prisoners in certain American prisons were in the habit of passing tobacco into the rectum to prevent themselves being forced to work. This causes an alarming reduction of the pulse. This is indeed a most dangerous experiment in physiology, and such criminals ought to know that tobacco is so poisonous that a weak solution such as that used for strangulated hernai formerly has been known to produce death in a few hours.

The One Grade Irish Pharmaceutical Licence.

In a letter to the *Pharmaceutical Journal* Mr. Barnard Proctor adopts exactly as we put it to our readers our view of the impolicy of the course decided upon by the Irish Pharmaceutical Council in establishing only one grade of dispensers in Ireland.

The Irish Pharmaceutical Society, he says, having concluded to establish only one grade of dispensers, and that under the title of Pharmaceutical Chemists, it is not much to be wondered at that they should aim at a lower standard of examination than that conferring the same degree in England. Had they set their standard as high as ours they would necessarily so limit their candidates that Ireland would remain insufficiently supplied with legally qualified dispensers; and if they are satisfied with a standard no higher than our minor or modified examinations, which are considered enough to show that a man is qualified as a dispenser, common sense and justice are outraged by their assumption of equality with the higher grade on this side of the Irish Sea.

So beautiful a combination of the sister arts of blundering and plundering is not often met with. While they are endeavouring to rob the title of Pharmaceutical Chemist of its hard-won value they are also blundering in a way that it will take a generation or more to recover from. Time will be required for them to see the folly of their ways, to retrace their steps, to obliterate as far as possible the effects of their present procedure, to cast men of sterling metal in the mould which long experience has proved to be satisfactory, and to allow the holders of Brummagem qualifications to die out before the Irish Society can look for reciprocity or meet with the approbation of honest and honourable men.

While concurring with Mr. Proctor as to the unwisdom of the exclusiveness of the Council, we are not, of course, supposed to countenance the ridiculous claim which the English Society sets up to a patent right in the title of Pharmaceutical Chemist. The name simply implies the carrying on of a particular trade which happens to be under control of an Act of Parliament, just as the words Medical Practitioner signify a duly licensed physician or surgeon. No college claims the title of Medical Practitioner as its trade-mark, nor can any one be made amenable for using such a title, and if the English Pharmaceutical Society considers it necessary to brand its licentiates with some distinctive title, it should obtain authority—if it does not already possess it—to confer the exclusive use of some such letters as L.Ph.S.Eng.

Death of Professor Boeck, of Christiania.

The eminent syphilographer, Professor Boeck, is dead. He was chiefly known as a warm advocate of the practice of syphilisation, which met with few to approve, still fewer to employ it, and a multitude to denounce it as barbarian and unscientific. Professor Boeck travelled about, and visited many countries, Britain included, in the endeavour to disseminate his views.

The New International Club.

On Saturday last "The Hanover Square International Club" opened its doors under favourable auspices. A very large and fashionable attendance of its supporters and subscribers assembled together in the tastefully-fitted and spacious drawing-room of the club and partook of an elegant luncheon expressly provided for the occasion. This high-class International Club has secured the patronage and support of a large number of noblemen and gentlemen, amongst others, Prince Edward of Saxe-Weimar, Count Gleichen, Prince Batthyany, the German, Danish, Turkish, Belgian, Italian, Spanish, United States, and various other Ambassadors, as well as a number of the English nobility, clergy, officers of the Army, Navy, Civil Service, Members of Parliament of all complexions, and professional and private gentlemen of all nations. It bids fair to become a great success, and most assuredly it will supply a want long felt in this metropolis. General J. B. Creach is the Hon. Secretary.

Dr. Warburton Begbie has kindly presented £105 to the Medical Benevolent College.

The London Fever Hospital contained last week 124 patients, of whom 109 were there for scarlet fever. There were 85 deaths from this disease in London and 56 from measles, with 70 from whooping-cough.

The Maharajah of Vezianagram has engaged an American lady to open a dispensary at Benares, exclusively for the benefit of native women; while the enlightened Sir Salar Jung has done the same thing in Hyderabad.

We are sorry to have to record the death of Mr. James Huston, late Aural Surgeon to Guy's Hospital. That gentleman was well known as an accomplished aurist. He had retired from the profession, and occupied himself with the study of philosophy and with questions of social science. He was a truth-loving and benevolent man, and his friends will long and deeply deplore his loss.

The Lettsomian Lectures of the Medical Society of London were commenced by C. Theodore Williams, M.A., M.D., F.R.C.P., Physician to the Hospital for Consumption and Diseases of the Chest, Brompton, on Monday last, and will be continued on the 17th and 31st, at 8.30 p.m. Subject—"The Influence of Climate in the Treatment of Pulmonary Consumption."

The great biennial prize of the French Academy has been given, with the necessary consent of all the other academies, to Dr. Paul Bert Professor of Physiology at the Sorbonne, and a deputy in the National Assembly, for his labours and published work "On the Influence of Barometric Pressure on the Phenomena of Life."

The Dublin Obstetrical Society will meet on Saturday, the 8th inst., at eight o'clock, at the College of Physicians, when the following communications are set down for reading:—

Dr. Johnston, Clinical Report of the Rotunda Lying-in Hospital, 1875.

Dr. McGuire, The Use of the Forceps in Undilatable Os Uteri.

Dr. Churchill, Some Cases of Retained Ovum.

Papers by Dr. Roe and Dr. A. V. Macan.

The election of a Professor of Botany in the University of Dublin takes place on the 29th inst. by the Provost and Senior Fellows of Trinity College. The emoluments

and advantages of the Professorship consist of the following items :—

1st. A fixed salary of £200 per annum.

2nd. An additional salary of £50 per annum, as Curator of the Herbarium.

3rd. An additional payment of £100 per annum, on condition that the Professor shall deliver Term Lectures and give Botanical Demonstrations to Students in Arts, as regulated by the Provost and Senior Fellows.

4th. Fees for Lectures, to Medical Students, £3 3s. each.

The vacancy in the Professorship takes place—in accordance with the School of Physic Act—every seven years, as a matter of rotation, and the outgoing Professor, Dr. Edward Percival Wright, will most probably retain his office.

Advantages of Early Treatment in Mental Diseases.

THE advantages derivable from an early treatment in mental disorders as represented by speedy recoveries have been fully borne out in Irish district asylums during the past year, for out of the cured and improved, 1,176 in number, 429 were discharged in the course of four months ; and in the interval of from four to eight months, 339, the total between both periods being 913, or two-thirds of the whole. Similarly as regards the recuperative powers of the mind in the earlier stages of life, the inspectors note that 361 were removed in perfect health who were under 30, and 569 between 30 and 40, constituting nearly four-fifths of the whole discharged. No doubt extensive as have been the advantages derived from district asylums in Ireland, they whuld be still more perceptible but for their being in many instances congested with hopeless cases ; during the past year between aged and demented, the idiotic and epileptic classes 339 individuals were received into them likely to become residents for their remaining existence, accumulating from one twelvemonth to another. The inspectors learn from the carefully compiled statistics before them, that the lunatics probably curable *on the 1st of* the present year were limited to 1,703, the *uncurable* to 5,140 ; idiots and epileptics to 742, making up an aggregate of 7,585 ; nevertheless the inspectors consider that by comparison they have no reason to complain, as in England the Commissioners report that in the public hospitals for the insane under their control, there are 30,098, who though affording little or no hope of recovery, still as a body require asylum treatment ; in other words, the incurable there predominate by twelve to one. The number of relapsed cases that had been previously in hospital once or twice before and admitted in the past year was 392, and from three to as many as six times, 37, a circumstance indicating the recurrent tendency of mental diseases, which would appear to be much stronger among females in whom moral causes predominate than among men, who, on the contrary, are more susceptible of physical influences. In 1,013 patients out of 5,360 an hereditary predisposition to insanity was traceable. We could obtain on this head no reliable information in 2,160 cases of the 7,585 in district asylums on the 31st December, 1874—within the close relationship of parents, brothers, sisters, and first cousins, there were out of the 1,013, 339 individuals.

Social Condition of the Inmates.

THE social condition of the inmates of Irish asylums as shown in the late report of the inspectors presents a remarkable feature in regard to marriage and celibacy, totally at variance with what obtains elsewhere, but particularly in England ; the married known insane amounting to only 2,082—the single to 5,164, or as 2 to 5—in England the married would appear to stand precisely in an almost inverse proportion.

THE nobleman whose death was announced in the telegram from Alicante is, says the *Hour*, no doubt the Earl of Aldborough, who has been living a very secluded life on the Canlabrian coast for some years. He was 67 years of age, and unmarried. He is the same nobleman whose name appeared for a length of time associated with Professor Holloway's advertisements. "The Earl of Aldborough and Holloway's Pills" was familiar to all newspaper readers twenty years ago. If his lordship has been using the pills ever since, either his constitution or the professor deserve credit for his having survived within three years of the allotted span.

Correspondence.

IRIDECTOMY IN CASES OF EXTRACTION FOR CATARACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems desirable that the ophthalmic fog complained of by a recent writer in your journal should be cleared up. The writer in question appears to condemn "*in toto*" the sacrifice of any portion of iris during the operation of extraction for cataract. While concurring with him so far as to admit that the adoption of iridectomy in every case is unnecessary and therefore unjustifiable, I think we must admit that there are a large proportion of cases in which it would be eminently unsafe to extract without removing a portion of iris. When a patient presents himself for extraction looking older than he is, wasted and tremulous from age or premature decay, with thin white locks, soft and sunken eyeballs, cornea of small diameter, rigid iris, and thin wrinkled skin, it is well to do an iridectomy either at the time of the operation or some weeks previously, the latter being the preferable course. The removal of a portion of iris is also an excellent safeguard against disaster if anything has gone wrong with the operation, such as excessive bruising of the iris, unavoidable retention of portions of cortex, or very marked tendency to prolapse, also in certain cases where we are obliged to operate upon immature cataracts. Those patients in whom these symptoms and accidents or other sinister complications are conspicuous by their absence may be spared the sacrifice of any portion of iris, and such cases yield by far the most brilliant results.

The removal of a portion of iris prevents prolapse, and takes away that portion of the membrane which is most bruised, and the first to become inflamed should ordinary reaction reach to that height. The saving of the pupil prevents the dazzling occasioned by a coloboma, corrects the aberration occasioned by sphericity of the cornea, diminishes irregular circles of diffusion, and largely compensates for the absence of the lens. For years past I have extracted in a large proportion of cases without iridectomy, and some of my patients declare that they can see as well as ever in their lives before.

Your obedient servant,
CHARLES BELL TAYLOR, M.D.,
Surgeon Nottingham and Midland Eye Infirmary.

Medical News.

Vital Statistics.—From the Registrar-General's returns we learn that during last week 4,726 births and 3,847 deaths

were registered in London and twenty other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1,000 persons living. The annual death-rate was 24 per 1,000 in London, 26 per 1,000 in Edinburgh, 27 in Glasgow, and 27 in Dublin. The annual rates of mortality per 1,000 during the same period in the other large towns were—Portsmouth 17, Norwich 23, Leicester 21, Wolverhampton 22, Sunderland 21, Bradford 24, Birmingham 27, Bristol 35, Sheffield 25, Leeds 29, Nottingham 23, Liverpool 28, Newcastle-on-Tyne 28, Manchester 35, Salford 38, Oldham 31, and Hull 20. The annual death-rate from the seven principal zymotic diseases averaged 4·2 per 1000 in these towns, and ranged from 1·5 both in Wolverhampton and Sunderland, to 8·2 and 11·2 in Manchester and Salford. Scarlet fever caused 28 deaths in Manchester and Salford, 21 in Bristol, and 15 in Leeds. Eight more fatal cases of fever were registered in Sheffield. Of the 6 deaths referred to fmall-pox in these towns, 4 occurred in Manchester and Salford, and 2 in Bristol. In London the 1,603 deaths included 85 from scarlet fever, 20 from different forms of fever, 12 from diarrhœa, and not one from small-pox. The deaths from the principal zymotic diseases were 23 below the corrected average number in the corresponding week of the last ten years. The 20 deaths referred to fever were so many as 30 below the corrected average number in the corresponding week of the last ten years; 4 were described as typhus, 11 as enteric or typhoid, and 5 as simple continued fever.

William Sands Cox, F.R.S., F.R.C.S., D.L.—This eminent provincial surgeon, whose death is announced, was a son of the late Mr. Edward Cox, a surgeon of repute in Birmingham, and was born in the year 1802. He began his medical studies with his father, and afterwards repaired to London, where he attended the practice of Guy's and St. Thomas's Hospitals, under Sir Astley Cooper, Mr. Green, and other eminent teachers in that distinguished medical school. The deceased was admitted a member of the College of Surgeons, Jan. 2, 1824, and in the following year was elected Surgeon to the Birmingham Dispensary. Mr. Cox, in conjunction with a few professional friends, founded the Queen's College and Queen's Hospital in Birmingham, and was for some years Professor of Surgery in the College, and Surgeon to the Hospital, which post he resigned in 1863, when he was appointed consulting surgeon. He was an accurate anatomist and fluent lecturer, distinguished alike for the clearness of his discourses and for the thorough knowledge of the science which he taught. Apart from his profession, Mr. Cox was well known and equally respected. He was a magistrate and deputy-lieutenant for Warwickshire, a Fellow of the Royal Society, a Fellow of the Royal College of Surgeons of England, a Fellow of the Chemical Society, and had contributed largely to medical literature.—*Standard.*

Contraction of the Trapezius, simulating Deviation of the Vertebral Column.—Cure.

I. C. Pravaz (*Gaz. Hebdom.*) records the following case:—

A young girl of fourteen was affected, after some severe mental disturbance, by a deviation of the spine, the bending of the vertebral column progressing gradually for four months, until scoliosis to a marked degree was attained. The dorsal vertebræ were most severely affected, the convexity above being to the right, with compensating deviation below. The upper and inner angle of the scapula was raised, the lower angle drawn strongly off. The upper part of the right trapezius was hard, and painful to pressure. By faradization of the anterior serratus magnus the scapula could be brought into position again. Galvanisation of the trapezius, douches, massage, all were of no avail. Hypodermic injections of a one per cent. solution of atropia to the extent of two to four drops twice a week were then ordered. No effect was felt from these until the dose had been increased to six drops which brought on general toxic symptoms. The spinal deviation began to amend from this time, and eventually the case ended in entire recovery.

Dr. Pravaz adds short notes of two similar cases coming under his care, both of which were successfully treated by atropia injections.—*Philadelphia Medical Times.*

On "Unconscious Cerebration."

Dr. Carpenter's theory of unconscious cerebration has been ably attacked by Dr. William W. Ireland, in the *Journal of Mental Science.* He observes, in closing:—

The recovery of lost names can be explained to a cer extent by the mental process of association, but not by " integrating and disintegrating mental processes." It be that a schoolboy who can say his lesson more readil the morning than on the evening before, is aided by fresher state of his brain; but we do not see that " fact," upon which Dr. Carpenter is asked to ponder v has been established on scientific evidence. How do know, for example, that "the disintegrating process" n takes place without a display of consciousness? Is th never any disintegration of the tissues of the brain with consciousness? Or may not consciousness accompany integration of the tissues? We can infer, from cert changes and reactions in the blood, that mental exertio followed by waste of the tissues of the brain, and that t waste is proportioned to the amount of work, but what the order and succession of changes which go on in the ne cells, or nerve fibres, during thought is, as yet, unknow us. When we can detect a desire with a chemical re-ag and when we can see an abstract idea through the mi scope, we shall, perhaps, have a true physiology of mind.

In any case the theory of "Unconscious Cerebrati derives no support from physiology, It is a child of old metaphysics, to be brought forward and repelled by study and analysis of mental operations, cognisable by ternal self-examination.

Evils from the Use of Wheaten Flour.

In the "Transactions of the New Hampshire Med Society, Dr. Ephraim Cutter, of Cambridge, Mass., bri a heavy indictment against flour as food. His article aim answer in the affirmative all the following questions:—

1. May it not be possible that the use of flour is a ca of the prevalence of diseases of the nervous system?
2. May it not be possible that the use of flour is a ca of the present lamentable and astounding prevalence of l erupting and decayed teeth?
3. May it not be possible that the use of flour is cause of the present prevalence of weak and diseased ey
4. May it not be possible that the use of flour is cause of the prevalence of baldness and premature g hair?
5. May it not be possible, that the so-called change the type of disease may, in some measure, be due to the of flour, so universal for the past forty years?
6. May it not be possible that the use of flour is one ca of the prevalence of some of our chronic diseases, as cata and consumption?
7. May it not be possible that the use of flour is one ca of the numerical decline in our native population in N England?

He concludes, that the universal and exclusive use flour, as found at the present time among the nations Christendom (as Liebig suggests), results in disaster to t human race, in these particulars.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are part larly requested to make use of a *distinctive signature or initials,* avoid the practice of signing themselves "Reader," "Subscrib 'Old Subscriber," &c. Much confusion will be spared by attentio this rule.

To our Subscribers in Ireland.—In consequence of the Index pearing as a Supplement in our present number, we are unable to g the usual Supplement on Poor-law medical affairs. It will, howe be given with the next number in the ordinary course.

Reading Cases.—Cloth lettered cases with strings to hold th numbers contained in each volume are now ready, and can be ha the offices of this journal in London, Dublin, or Edinburgh, or thro any bookseller, price 2s. 6d.

Heart Disease.—Dr. James E. Pollock's paper "On Cer Varieties of Heart Disease, with reference to Prognosis and Tr ment," will be continued in our next.

Dr. Abrath's letter arrived as we were going to press.

Royal College of Surgeons [of London.—The Gulstonian l tures will be delivered at the College by Dr. Shepherd on March 10, 17, at 5 o'clock. The Croonian Lectures by Dr. Dickinson on M 22, 24, 29, at the same hour. The Lumleian Lectures by Dr. Habersh on March 31, April 5 and 7, also at 5 o'clock. The subjects of t lectures will be announced by us the week prior to their delivery.

Compensation with a Vengeance.—A medical man of Mont has recently sued his landlord for 20,000 dols. for illness caused, alleges, by the unhealthiness of the house in which he resides. How verdict has turned we have not yet heard, we should imagine in fav

of the landlord, not necessarily as a matter of justice, but because, if a precedent were once established, every convalescent and the relatives of persons deceased would find illness and even death a profitable business, and the cause would, by some circuitous route, be traced to the door of each unfortunate landlord.

Obstetrical Society of London.—This evening, at 8 p.m., the Annual Meeting and Election of Officers and Council will take place. After the President's Address, Dr. Routh will read "A Case of Extra-Uterine Fibroid successfully treated by Gastrotomy," and Dr. John Williams, "On the Mechanical Action of Pessaries."

Army Surgeon.—An examination of candidates for commissions in the Army Medical Department will be held at the University of London on the 14th prox. The list closes ten days previously.

Mr. Geo. Tatham will please receive our best thanks.

Mr. Vincy.—We do not know the Analytical Tables to which you refer; the author named has certainly not published any.

Dr. E. S.—Not suitable for our columns.

Communications, Enclosures, &c., have been received from—Mr. Jolliffe Tufnell, Dublin. Dr. Francis R. Hogg, Delhi, India. Mr. Fleming, Chatham. The Director-General of the Army Medical Department. Dr. W. Moore, Dublin. Dr. E. Lane, Kirton. Dr. Atherton, Thatto Heath. Mr. Porter, Dublin. Mr. Field, London. Professor Ulrich, Bremen. Dr. Bartley, Weston-super-Mare. Dr. Birchenall, Macclesfield. Prof. Tichborne, Dublin. Dr. Altschul, London. Dr. Alfred Sheen, Cardiff. Dr. Hughlings Jackson, London. Dr. Dunglison, Philadelphia. Mr. Napier, London. Mr. Barker, London. Dr. Harrison, Ilkley. Mr. Gaskoin, London. Mr. Raulier, Paris. Mrs. Fayrer, London. Mrs. Baines, London. Mr. Jabez Hogg, London. Dr. Kirby, London. Major Borrowes, Naas. Dr. Watson, Glasgow. Dr. Lombe Atthill, Dublin. Mr. McLintock, Dublin. Dr. Henson, Manchester. Mr. H. Gray Croly, Dublin. Dr. Davys, Cremona. The Registrar of the Royal College of Physicians of London. Mr. D'Orsey, Bayswater. Dr. Harris, Dublin. Mr. Tallach, the Howard Association. Dr. Gray, Speenhamland. Dr. Barlow, Manchester, &c., &c.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Practice of Midwifery. By D. Lloyd Roberts, M.D. London: J. and A. Churchill.

Observations de Metrorrhagies. By le Dr. Guéneau de Mussy. Paris: H. Lauwereyns.

The Practitioner for December. Macmillan.

The Veterinary Journal for December. Baillière.

The Geography of Disease in England and Wales. By Alfred Haviland, M.R.C.S. London: Smith, Elder, and Co.

VACANCIES.

Central London Sick Asylum. Assistant Medical Officer. Salary, £100 per annum, with board and residence. Applications to be addressed to the Clerk, Highgate Infirmary, N.

St. Luke's Hospital for the Insane, London. Clinical Assistants.

Derby Infirmary. Assistant House Surgeon. Board, lodging, and washing, but no salary. Address the Secretary.

Huntingdon County Hospital. House Surgeon. Salary commencing at £60, with board. Applications to Mr. Oldham, Surgeon, Huntingdon.

Liverpool Ear and Eye Infirmary. House Surgeon. Salary, £80, with board. Apply to the Hon. Treasurer, 8 Knowsley Buildings, Liverpool.

Birmingham. Assistant Workhouse Medical Officer. Salary. £100, with furnished apartments, &c. Endorsed applications to be sent to the Parish Offices, Paradise Street.

Bolton Union. Assistant Medical Officer of Workhouse. Salary, *£100, with* board and residence. Endorsed applications to the Clerk *of the Board.*

APPOINTMENTS.

Allden, J. H., M.R.C.S.E., House Surgeon to the London Hospital.

Anderson, R. J., M.D., Demonstrator of Anatomy at Queen's College, Belfast, vice Charles, appointed Professor of Anatomy and Physiology at Queen's College, Cork.

Colby, W. T., M.R.C.S.E., Medical Officer for the Malton District and the Workhouse of the Malton Union, Yorkshire.

Cooper, W., M.R.C.S.E., Medical Officer for the Farnworth District of the Prescot Union, Lancashire.

Duke, R. R., L.R.C.S.I., Medical Officer for the Western District of the Cerne Union, Dorsetshire.

Flood, Mr. F. P., an Assistant Resident Medical Officer to the General Infirmary, Leeds.

Frobisher, Mr. W. M., an Assistant Resident Medical Officer to the General Infirmary, Leeds.

Inglis, A. M., M.D., a Consultiug Physician to the Worcester Infirmary.

Irvine, J. P., M.D., M.R.C.P.L., Lecturer on Forensic Medicine at the Charing Cross Hospital Medical School.

Lace, J. I., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Officer for the Lamplough District of the Whitehaven Union.

Metcalfe, Mr. P. H., an Assistant Resident Medical Officer to the General Infirmary, Leeds.

Pye-Smith, R. J., L.R.C.P.L., M.R.C.S.E., House Surgeon to the Royal London Ophthalmic Hospital.

Reid, W., M.B., C.M., House Surgeon to the Stroud General Hospital.

Thursfield, W. N., M.D., M.R.C.S.E., Medical Officer of Health for the Newport Urban Sanitary District, Salop.

Walter, W., B.A., M.B., L.K.Q.C.P.I., House Surgeon to the North Staffordshire Infirmary, Stoke-upon-Trent.

Deaths.

Ball.—On the 26th November, at Little Sutton, Cheshire, J. W. Ball, M.D., M.R.C.S.E., aged 62.

Crookenden.—On the 21st December, at Lincoln House, Kensington, Dr. H. Crookenden, aged 57

Fothergill.—On the 19th December, at Stoke Newington, John Fothergill, Surgeon, aged 69.

Harrison.—On the 12th December, at the Lunatic Asylum, Douglas, Isle of Man, A. R. Harrison, M.D., Resident Medical Superintendent, aged 40.

Hinton.—On the 16th December, at St. Michael's, Azores, J. Hinton, M.R.C.S.E., late of Savile Row, aged 51.

Llewellyn.—On the 14th December, at Newington Causeway, Wm. B. J. Llewellyn, L.R.C.P.Ed., aged 46.

Sargent.—On the 21st December, at the Suffolk Lunatic Asylum, Melton, Geo. Sargent, M.R.C.S.E., aged 30.

Seward.—On the 23rd December, Thos. Seward, M.D., of the 90th Regt. Light Infantry, late of Westrn, near Petersfield.

Speirs.—On the 25th December, at St. Vincent Street, Glasgow, John Speirs, L.F.P. & S. Glas.

Synnott.—On the 15th December, at Bishop-Auckland, Patrick A. Synnott, M.R.C.P.Ed.

Wetherell.—On the 22nd December, at Highgate, N. T. Wetherell. M.R.C.S.E., aged 75.

Williams.—On the 26th December, at High Street, Bangor, Owen T. Williams, L.R.C.P.Ed., M.R.C.S.E., aged 32.

MEDICAL SOCIETY OF LONDON, Founded 1773.—11 CHANDOS STREET, CAVENDISH SQUARE, W.

SESSION 1875-76.

The LETTSOMIAN LECTURES will be delivered by C. THEODORE WILLIAMS, M.A., M.D., F.R.C.P., Physician to the Hospital for Consumption and Diseases of the Chest, Brompton, on MONDAY, JANUARY 3rd, 17th, and 31st, 1876, at 8.30 p.m.

SUBJECT—"The Influence of Climate in the Treatment of Pulmonary Consumption."

C. THEODORE WILLIAMS, M.D. } Hon. Secs.
RICHARD DAVY, F.R.C.S. }

ARMY MEDICAL DEPARTMENT,
1st January, 1876.

AN EXAMINATION of CANDIDATES for COMMISSIONS in the Medical Department of Her Majesty's Army will be held in London on the 14th FEBRUARY, 1876, and following days. Candidates having the necessary qualifications to practise Medicine and Surgery under the Medical Act, and who are not under 21, nor above 28 years of age, are eligible to attend.

Application for the printed Schedule, prior to the Examination, should be made in writing, without delay, to the Director-General, Army Medical Department, War Office, London. As the list will be closed on Saturday, the 5th February, all schedules and necessary certificates must be returned on or before that date. There will be 40 appointments offered for competition.

(Signed) W. M. MUIR, Director-General.

CARLOW UNION.
BAGENALSTOWN DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The Committee of Management of the above Dispensary District will, at their Meeting to be held at the Dispensary, Bagenalstown, on WEDNESDAY, the 19th day of JANUARY, 1876, at One o'clock p.m., appoint a duly-qualified MEDICAL OFFICER for the District, at a Salary of £100 per annum, exclusive of £20 per year as Sanitary Officer and Vaccination Fees.

The person appointed will be required to reside in the town of Bagenalstown, or immediate neighbourhood.

Applications, with Testimonials, &c., to be lodged with Mr. JOHN MAGRATH, Bagenalstown, Honorary Secretary, not later than 12 o'clock noon on the day of election.

Personal attendance of Candidates necessary.

By Order, EDWARD L. JAMESON,
Clerk of the Union.

Board Room, Carlow, 30th December, 1875.

ONE MILLION STERLING
Has been paid as
COMPENSATION FO DEATH AND INJURIES
Caused by
ACCIDENTS OF ALL KINDS,
By the
Railway Passengers' Assurance Company,
Hon. A. KINNAIRD, M.P., Chairman.
PAID-UP CAPITAL AND RESERVE FUND, £180,000.
Annual Income, £200,000. Bonus allowed to Insurers of 5 years' standing
Apply to the Clerks at the Railway Stations, the Local Agents, or 64 CORNHILL, and 10 REGENT STREET, LONDON.
WILLIAM J. VIAN, Secretary.

BUTLER'S MEDICAL HALL,
53 & 54 LOWER SACKVILLE STREET,
DUBLIN.
ESTABLISHED A.D. 1817,
For Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of
WILLIAM STARKEY, M.D.,
Licentiate Apothecary.

J. CROSS & SON
18, HOLBORN HILL,
LONDON, E.C.
ESTABLISHED 1813.
ENGRAVERS, PRINTERS, AND LITHOGRAPHERS.
DISPENSING LABELS.
DISPENSING AND CHEMICAL STOCK LABELS
1s. 8d. per 1000.
DITTO, WITH NAME & ADDRESS
from 2s. per 1000
LABELS CUT BY MACHINERY.

XMAS ACCOUNTS

MERRITT and HATCHER send, post free, on application, a variety of Samples and Prices of MEDICAL BILL FORMS, by which a great saving of time in making out accounts is effected.

Merritt and Hatcher, Printers, 2 Grocer's Hall Court, Poultry, London, E.C.

SURGICAL SOCIETY OF IRELAND.—The next meeting of the Society for the present Session will take place on FRIDAY evening next, the 7th day of January, 1876. Chair will be taken at half-past eight o'clock, precisely.

By Order,
B. WILLS RICHARDSON, F.R.C.S.I., } Hon. Secs.
JOLLIFFE TUFNELL, F.R.C.S.I., }
Royal College of Surgeons, December, 1875.

TRINITY COLLEGE, DUBLIN.—SCHOOL of PHYSIC in IRELAND.—Pursuant to the provisions of the School of Physic Act, 40 Geo. III., ch. 84, and Amendment Act, 30 Vict., ch. 9: Notice is hereby given that the Professorship of Botany in the School of Physic will become vacant on the 23rd January, 1876; and that on Saturday, 29th January, the Provost and Senior Fellows of Trinity College will, at the hour of twelve of the clock (noon), in the Board Room of the said College, proceed to elect a Professor of Botany.

The Emoluments and advantages of the Professorship consist of the following items:—

1st. A fixed salary of £200 per annum.
2nd. An additional salary of £50 per annum, as Curator of the Herbarium.
3rd. An additional payment of £100 per annum, on condition that the Professor shall deliver Term Lectures and give Botanical Demonstrations to Students in Arts, as regulated by the Provost and Senior Fellows.
4th. Fees for Lectures, to be regulated from time to time by the Provost and Senior Fellows.

N.B.—The Fees at present are—
Lectures to Medical Students £3 3 0

Graduates in Arts, and Students whose names are on the College books, are admitted to the Medical Course without payment of Fees.

All Candidates are required to send their names, with the places of their education, the Universities where they have taken their Medical Degrees (if any), and the places where they have practised (if any), to the Registrar of Trinity College, Dublin, and the Registrar of the King and Queen's College of Physicians in Ireland, on or before Saturday, 22nd January, 1876.

Candidates wishing for further information are requested to communicate with the Rev. Dr. HAUGHTON, Medical Registrar, Trinity College, Dublin.

ANDREW S. HART, Registrar, T.C.D.
J. MAGEE FINNY, Registrar, K. & Q.C.P.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office, 40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

ROTUNDA LYING-IN HOSPITAL, DUBLIN.

Master:
LOMBE ATTHILL, M.D.

Assistant-Physicians:
ARTHUR V. MACAN, M.B. RICHARD D. PUREFOY, M.B.

This Hospital (the largest Chartered Clinical School of Midwifery in the British dominions) contains Wards for the treatment of Diseases of Females, in addition to the Wards appropriated to Lying-in cases.

A large Dispensary for the Diseases peculiar to Women is connected with the Hospital.

Clinical Instruction in Midwifery, and the Diseases of Women, is given daily.

The Pupils are privileged to attend the Cow-Pock Institution, Sackville Street and York Street.

The Lectures are recognised by the Royal College of Surgeons in Ireland, London, and Edinburgh; the King and Queen's College of Physicians; the Apothecaries' Hall of Dublin and of London; the Army and Navy Medical Boards; and all other Licensing Bodies.

The Diploma from this Hospital is recognised by the Poor-law Commissioners as a qualification in Midwifery for all Hospitals and Dispensaries under their control in Ireland.

Accommodation is provided for a limited number of Intern Pupils.

Pupils can enter at any time.

Applications to be made to Master or Assistant-Physicians, at the Hospital, Rutland Square.

The Medical Press & Circular.

ON CERTAIN VARIETIES OF HEART DISEASE, WITH REFERENCE TO PROGNOSIS AND TREATMENT.

By Dr. James E. Pollock, F.R.C.P.,

Senior Physician to the Brompton Hospital for Consumption.

(*Continued from page 467 of last Vol.*)

The final results of heart disease are of course manifested in *congestion* of the two great systems of the circulation—*pulmonary* and *systemic*. To the latter belongs *cerebral apoplexy*—of which I shall speak briefly—and in considering the lesions of each valve separately, I shall refer to the effects on the two systems. I shall endeavour to exhibit the symptoms and progress in the order of their frequency and importance.

Simple aortic obstructive disease may exist for years with but slight inconvenience to the system. The result, as is well known, is hypertrophy of the left ventricle, and if the ventricle increases in power so as to be able to propel a sufficient quantity of blood into the aorta the system does not materially suffer. It is a rare disease, and the progressive thickening of the left ventricle is an admirable instance of compensation. Thus this affection, when simple, is neither a cause of systemic nor of pulmonary congestion, and excepting slight dyspnœa and occasional faintness, the patient does not suffer. (In 116 cases of systemic congestion observed, only 16 were purely aortic.—*Blackiston*). It was formerly supposed by Hope and others that *cerebral congestion* was directly caused by the hypertrophy of the left ventricle, and it is also the opinion of Sir G. Burrows; but I cannot support this view, as the additional propulsive power gained by the thickened ventricle is expended on overcoming the obstacle in the valve, and cerebral congestion is caused, like all the other congestions in heart disease, by impediment to the return current rather than by the force of the ventricle.

The *prognosis* in simple obstructive disease of the aortic valves may be good for time so long as the ventricle continues to act with power. And such cases have lasted under my observation for very many years. In my earlier days I have seen them treated by blood-letting, by digitalis used as a cardiac sedative, and by setons over the heart; those remedies being used to subdue hypertrophy and its supposed fatal result of driving the blood with too much force on distant organs; but it is now acknowledged that the hypertrophy is a healthy compensatory process, and that the inconvenience of an augmented supply of blood to the brain, lungs, liver, and kidneys is only fraught with danger when a venous stagnation prevents its free return from those organs. I am not aware that sudden death ever results from obstructive aortic disease.

Aortic regurgitation is accompanied by more mechanical difficulties and proportionate danger than the simple obstructive thickening of the valves. The reflux of the blood into the ventricle meets the blood entering from the auricle, causing engorgement of the pulmonary veins and of the lungs. The obstruction in the lungs excites hyperaction of the right ventricle, and ultimate dilatation, while the left ventricle becomes mechanically dilated by the reflux from the aorta. It is in fact the seat of two currents of blood from opposite sides—from the aorta and from the auricle. Death in such cases is commonly either from pulmonary engorgement, pneumonia, apoplexy, or œdema, or it occurs suddenly from cerebral syncope. I believe the sudden cases are due to failure of the left ventricle to supply the brain, and this result is most common where the ventricle has undergone degeneration of its walls. The danger of an aortic regurgitation is therefore very great, sudden collapse, and fatal fainting being common. I need scarcely remind you also that obstructive and regurgitant disease may coexist in this as in all the valves, when the symptoms are more complicated and more dangerous.

In speaking of these valves separately, it is not to be forgotten that in advanced cases it is rare to find a single lesion, although it may be convenient to study their results separately. Thus the mitral valve is found diseased in combination with the aortic in numerous instances, and the same is to be remarked of the ventricles. It is rare to find one ventricle only dilated, no matter what the leading

form of disease may have been. The dangers then arising from diseased aortic valve when the affection is single are cerebral and pulmonary, and not commonly that secondary systemic congestion which results in cardiac dropsy.

Mitral obstructive disease, or stenosis, is a rare form, as a single affection. The presystolic murmur which has lately attracted so much attention from the labours of several observers (Hayden, Fagge, Walker, Waters, and Semple) is characteristic, and was unknown to the earlier students of heart disease. It is synchronous with the auricular contraction and the period of silence in the heart's rhythm, and is caused by the obstruction in the onward current from the left auricle through the mitral valve. It thus illustrates the natural action of the heart —the auricles contracting silently in health, the onward current through the mitral being unaccompanied by sound. The order of events in mitral contraction appears to be that the left ventricle imperfectly supplied with blood contracts, and the left auricle becomes overdistended as the blood pours in from the lungs. The engorgement extends back to the lungs, thence to the right ventricle, which becomes hypertrophied. Thus the lungs become doubly engorged, by the return current obstructed and by an augmentation of the supply current. From this state of things pulmonary apoplexy, pulmonary congestion, and œdema (one or other) must certainly result. And when the lung congestion is propagated backwards to the right ventricle, if its dilatation occur, and the right auricle be blocked, systemic venous congestion results, and so cardiac dropsy.

The affection is rare, and therefore must occupy a small place in the history of valvular disease; but it is to be remarked of it that this lesion again illustrates the fact that the extreme gravity of all diseases of the valves of a chronic nature is only reached when venous stagnation occurs.

Mitral regurgitation is much more common and important. The blood regurgitates into the left auricle, which dilates from pressure of ventricle, and the obstacle is propagated back to the lungs. Consequently pulmonary congestion, hæmoptysis, apoplexy, pneumonia and œdema are frequent results. The right ventricle labours to overcome the obstacle at mitral valve. In a manner the two ventricles become opposed to each other with the lungs intervening. The one to yield first *is the right*, for I find that in 84 fatal (Blakiston) cases of pulmonary congestion attenuation of the right ventricle was found in *all*, and of the left in 17 only, while both were thinned and dilated in 8. But as the disorder of circulation progresses the left invariably yields also, and those figures do not truly represent the ultimate effects of mitral regurgitation, for we seldom indeed find after death dilatation of only one ventricle. When the disease reaches the right heart, and such distension of its chambers occurs as leads to its engorgement with venous blood, the systemic events of extreme gravity are instituted, which end in cardiac dropsy. Thus we see that mitral regurgitation acts indirectly but surely in producing systemic congestion by first producing pulmonary stagnation or block. If death does not occur from dyspnœa, pulmonary apoplexy, congestion, or pulmonary œdema—which is the first order of events—it ultimately takes place in the slower form of obstructed return of venous blood to the right side of the heart.

The right cavities and valves of the heart are rarely diseased primarily, but they play an important part in the history of valvular disease, for it is when they become charged with venous blood through the medium of lung congestion that the final disasters of systemic congestion occur.

We need not examine obstructive and regurgitant disease of the pulmonary valves, on account of the rarity of their occurrence. *Tricuspid insufficiency*, allowing of regurgitation, is, however, of great importance. It occurs in a large number of cases of dilated right ventricle, and is often caused by shortened cordæ tendineæ, or adhesion of a valve to the ventricle. It is a direct cause of venous congestion. In 91 out of 108 cases of dilated right ventricle, Blakiston found *tricuspid insufficiency*, and the orifice dilated often to a circumference of 6 inches, its average circumference in health being 4 or 4½ inches. The venous pulsations in the neck so often seen in advanced cases of heart disease are significant of this lesion, and also of the general venous stasis which occurs. When such cases do not die rather suddenly of fatty degeneration of the ventricles, a pulmonary congestion propagated back to the right chambers of the heart (and itself originated in mitral patency) generally proves fatal by systemic congestion and dropsy. The prognosis of *tricuspid* regurgitation must be very guarded, as a fatal result may occur at any time, and particularly as cerebral congestion is a frequent result.

Before proceeding to consider the treatment applicable to chronic valvular disease, I would recapitulate certain propositions.

1. Primary disease of the left valves and chambers of the heart is most common, but ultimate systemic congestion is reached when the right chambers become enlarged and the walls thinned.

2. Pulmonary congestion is prior in order of events to the congestion of the systemic organs, but it is propagated backwards to the right heart, and thence to the general venous system.

3. Both pulmonary and systemic congestion arise not so much from the force of the arterial blood thrown into the lungs or capillaries by the hypertrophied ventricles as from obstruction of the return current; hypertrophy, therefore, although it may aggravate a congested organ by increasing arterial tension, can never cause a congestion *per se*.

4. Death without disturbance of the systemic or pulmonic circulation is generally sudden, as syncope from imperfect supply to the brain, the ventricle walls being fatty, or from cerebral or pulmonary apoplexy.

5. The valvular obstructive diseases may be extensive without causing death.

6. The valvular regurgitant diseases are more formidable, as leading directly to dilatation of the ventricles and auricles.

7. Hypertrophy of the walls of heart cavities is always compensatory, and seldom a cause of danger.

8. Dilatation of the walls of the cavities, with progressive loss of muscular power, is the most formidable of all the affections, and it is reached invariably as the final stage of all chronic valvular disease.

9. Dilatation and thinning of walls is the immediate antecedent of venous congestion, and venous congestion is the final cause of cardiac dropsy. It will be convenient to trace back the effects of venous congestion on the system.

The right heart having become dilated, and incapable of acting on the whole of the venous blood entering it, the venæ cavæ are the first to suffer; cerebral congestion results. On the inferior cava depends the whole portal system, so that the liver is congested, and often enormously enlarged, the renal veins are engorged, and the kidneys secondarily, so that their secretion is greatly diminished, and the urine becomes albuminous. The mesenteric system, the iliac veins, the femoral and saphena show their engorgement by ascites (and conjointly with the renal congestion as a cause), by anasarca of the integuments, which gradually spreads over the whole body. The pulmonary system, as has been said, is blocked early, generally through mitral regurgitation and dilatation of the ventricles; hence pulmonary œdema will often be found over the bases of the lungs, even before the ankles pit on pressure; but when the latter symptom occurs it commonly means distress of the right cavities of the heart and incipient venous overflow.

Now this is the state of things which we are often called on to remedy, and I need scarcely recall to your memory the pictures of cardiac distress which we have so often witnessed. Your patient sits stooping forwards with elbows on the arms of a chair; his breathing is short, and his words are broken and anxious; he points to the ster-

num as the seat of his distress; his colour is congested, red, or perhaps dusky, and his lips dark. He says he has not slept for days and nights, and he points to his uncovered feet, cold, swollen, and pitting more or less deeply on pressure. Perhaps even the genitals and abdominal walls are swollen. If he fall asleep, which will often happen, even while you are talking to him, he starts up with great distress, and gasps. His urine is scanty and albuminous; perhaps his liver is enlarged; a subcrepitant sound over one or both lungs indicates œdema of those organs, or dulness over the base indicates serous effusion into the pleura. This is, of course, the picture of an advanced case, but it is typical, and the earlier symptoms may only be congested face, colour scarcely dark, dyspnœa,, and slight pitting of ankles; the pulse may be full and tense, or yielding and partly filled, or dichrotous, varying with the valve affected. The whole of the conditions described are due to two main causes—

1. Mechanical stasis of the blood, chiefly in the venous canals and right heart, and resulting capillary congestion of all parts of the body.

2. Of insufficient power on the part of the heart cavities to propel the blood.

If we could find remedies to meet these two conditionss we should certainly at once relieve, and possibly cure, the patient. At all events, life would be saved for that time.

Now it is remarkable what nature does: let us observe carefully, and follow in her steps. She makes use of two means of relief—first, by a hæmorrhage, it may be from the lungs, or from the stomach, and next by serous effusions into the cavities, into the cellular tissues, *anywhere* as an overflow, to relieve the bursting pipes. Next she strengthens the working muscles, which are labouring to drive the blood on through the heart's chamber, and we have all seen the surprising thickening of the heart walls which takes place.

Now, have we any remedies like these?

First, dare we lessen the quantity of the blood circulating with such difficulty through the veins?—filling up the great organs and slowly reaching the right auricle? What would be the result? 1. Immediate relief to the over-charged right chambers of the heart. 2. Lessened arterial tension, diminished capillary engorgement, and the pulmonary system relaxed so that with lessened quantity of blood the lungs are enabled to transmit at length some properly aerified blood to the left ventricle for systemic use. Your patient draws a deeper breath—his colour improves—perhaps he sweats—the result of lessened tension of the arterioles—and he lies down and *sleeps!* This is a sleep which you have failed to obtain by opium, or morphia, or chloral. It is the sleep of a brain supplied with better quality of blood.

What are the objections?

1. "By blood-letting you weaken the tone of the ventricle, which you would fain strengthen." I reply that by withdrawing a portion of the blood which is causing over-distension, you permit of more free action of the walls of the heart.

2. "You exhaust your patient and hasten a fatal issue." This remark applies only to very advanced cases, where of course blood-letting is inapplicable. But is it advisable or not in the early stages of heart congestion?

Some months ago my friend Dr. English, of Brompton, asked me to visit a middle-aged gentleman who had a mitral regurgitant murmur. Doubtless he had had it for some time, but he never discovered anything wrong in his health till about a fortnight before, when he got dyspnœa, which gradually increased. We found a stout, muscular man, of florid complexion, gasping for breath, his face much congested. He was sitting up, and had not slept for several nights; his ankles pitted; his urine was scanty, not albuminous. He complained much of tension over the abdomen, and of tightness at the sternum. He has a mitral regurgitant harsh murmur, strong action of the ventricles, cardiac dulness increased transversely, but not to an extreme degree. On carefully regarding this case I proposed to take blood from his arm, and to this Dr. English agreed; but as the family demurred we proposed to ask Sir W. Gull. We did not communicate to him our proposed remedy. After seeing him his first remark was, "I have not ordered blood-letting for some time, but that is a case for trying it!" We bled that patient to ʒxx. with immediate relief; and he continued relieved for a long time, although of course we could not cure his mitral murmur; yet I believe we delayed the dilatation of the ventricles and subsequent congestions.

I believe, then, that there are certain mechanical conditions (so to speak) in which the quantity of blood to pass through the heart is in excess of the heart's power, and that in such cases we may relieve our patient and indefinitely postpone the final stages of cardiac dropsy. I know it is said that venesection diminishes all the solid constituents of the blood but one—and that is fibrin—but I do not hold this to be an argument against lessening the quantity of a fluid, quantity being exactly the difficulty with which we have to deal.

A preliminary blood-letting also makes all other remedies act better, as diuretics and purgatives, and this probably by lessening arterial tension and capillary engorgement. Of course I would not advise it if the patient were nearly exhausted, the colour livid, the pulse faint, and serous congestion considerable. But I do propose and practise it when the colour is florid, the pulse tense, the heart murmur loud, and the dilatation of the cavities not extensive. I should be very glad to elicit the views of the members of this Society on this point.

The second indication in treating the results of valvular obstruction is to strengthen the walls of the heart, and so assist the cavities in emptying their contents. We have no remedy which acts on the veins, as they are devoid of involuntary muscle, and the means to be applied must be mechanical, that is, either a direct blood-letting or by unloading the organs from which they convey the blood, as purgatives which unload the hepatic system and deplete by inducing watery evacuations from the intestinal tube. But we have remedies which act on involuntary muscular fibre, and these can be used with great success to restore tone to the dilated heart cavities.

I will briefly state from various authorities—Traul e, Withering, and Brunton—the physiological effects of digitalis on healthy animals given in repeated doses. Digitalis acts directly on the regulating apparatus of the heart and slows the pulse without loss of tension. It stimulates the musculo-motor nerves, and gives increased force to the cardiac contractions. The impulse is increased, and becomes abrupt and strong, and a systolic murmur is developed (at the mitral). It also contracts the arterioles and increases arterial tension, and contracts the capillaries. Pushed to poisonous doses, the pulse becomes more rapid, a quick beat being interpolated between the slower beats. Arterial tension falls, the capillaries dilate, and resistance being lessened, the heart's action becomes violent. After death the heart is found contracted, the arteries empty, and the veins full. The cause of death appears to be the stopping of the heart's action and defective supply of blood to the nerve centres. It further appears to act on all involuntary muscular fibre, and contracts the uterus like ergot. By its continued use the temperature falls, and the respirations diminish. I will not delay to enter on the question of the *modus operandi* of digitalis, as to whether it acts through the vagus or sympathetic, but I presume that its effects are on both, and especially on the cardiac ganglia, as in poisonous doses the rhythm of the heart is altered and the unison of action of the spiral fibres of the ventricles is lost.

Now it is plain that, theoretically, we have here a most powerful agent in counteracting the effects of dilatation of the heart, and giving tone to its contractile action, and in practice I think we may say that it has realised our expectations.

Digitalis assists hypertrophy, or the compensatory power of the heart, and directly counteracts dilatation. It also regulates the heart's action and slows it. Digitalis is counterindicated of course in aortic obstructive disease,

and in mitral stenosis, unless dilatation of the left ventricle has evidently taken place. By its action on the right ventricle in such case it would further embarrass the lungs. Niemeyer and Fothergill both object to the use of digitalis in constricted orifices and hypertrophy. But in the regurgitant affections of the valves it is eminently useful, and as these are the most common and most fatal of the valvular affections, its importance as a remedial agent is indeed very great.

It has been remarked, and I agree in the observation, that it seldom succeeds in cases of tight, hard pulse, and florid complexion, with warm skin, but is most applicable and successful where the impulse is feeble, the intermitting, where the face is pale and the lips livid (Withering, "Trans. Royal Soc.," 1865). These are, indeed, the cases in which we are almost in despair of rescuing our case, for ordinary stimulants only rally the heart's action for a short period.

The action of digitalis also as a diuretic is very marked, and in some cases it wonderfully increases the renal secretion. Its action, therefore, on the anasarca is most useful. Theoretically, we are somewhat at a loss to understand this, as it causes contraction of the arterioles, and so would lessen the supply of blood to the kidney; but I am inclined to agree with Dr. Fothergill, that its action is directly on the Malpighian tufts.

It is remarkable that digitalis is not always diuretic in health, and in large poisonous doses it has caused suppression of urine; but all authorities agree that it is eminently diuretic in cardiac cases.

In consultation I am often reminded of the dangers of giving digitalis by some of our brethren, who still hold the old ideas, and deny that it is a cardiac tonic. Although I give it in full doses, and for a considerable length of time, I have never witnessed any ill results. Of course, if it be given in such doses as will slow the pulse, it requires watching by the medical attendant. I also never give it in well-marked cases of fatty degeneration with very slow and irregular pulse. Here it might cause rupture of the weak fibres of the ventricle and sudden death. I believe all authorities give a caution as to its use in such cases. As a diuretic I give ℥ij. to ℥iv. of the infusion every three hours, and I greatly prefer an infusion of the leaves when fresh. I think it acts well alone, but nitrous ether arrests its action on the kidney, and tinct. ferri perchlor. is an excellent combination. The powdered leaf (if *fresh*) with squill (which is another cardiac poison) is an excellent adjunct, given in pill, and I believe the addition of a grain of blue pill to each dose assists its action on the kidneys.

The following case, condensed from many notes, illustrates the use of digitalis and the ordinary events of mitral disease:—

Mr. J., æt. 49, consulted me in October, 1870, for dyspnœa, to which he had not been accustomed; cough, with moderate expectoration, to which he was subject in winter. He was a healthy, temperate man, with no hereditary tendency to rheumatism or heart disease. He was much exposed to weather in his occupation as farmer. There was crackle at the bases of both lungs. The cardiac sounds were diffused over a rather wide area of the chest. He was treated with iod. potass. and alkalies, and got better. A month later he had jaundice, and the liver became enlarged. He was treated with purgatives (mercurial) and relieved; the liver returned to its natural size. At the end of November he had systolic harsh murmur at apex (mitral regurgitant).

In March, 1871, his dyspnœa was worse; urine became scanty, high coloured; 1½ pints in 24 hours (no albumen, no casts); harsh systolic apex murmur. Squill and digitalis in pill night and morning, and perchloride of iron mixture. Crepitation, both lungs at base.

December, 1871.—Urine albuminous, very scanty; legs and feet swollen; well purged by pulv. jalapæ (with calomel, gr. i.); felt weak after the powder, but urine became non-albuminous, and swelling subsided.

January, 1872.—Urine reduced to a pint; coagulable; legs and body swollen, and dyspnœa increased, so that he sat up day and night; some ascites; taking iron and nitrous ether; was well purged by elaterium, but little relieved.

February 12.—Infusion of digitalis, ℥ij., given every three hours, day and night, and continued, with gradual increase in quantity of urine, and steady diminution of the dyspnœa till March 7, when he was able to go downstairs and walked up again.

On March 14 urine no longer albuminous, 2½ pints; anasarca less; body still swollen; dyspnœa less; harsh mitral murmur; crackle over bases of lungs.

March 21.—Swelling of limbs and body gone; urine normal.

May 4.—Urine about a quart; does not complain of his breath; slight pitting of feet at night; goes about farm on horseback; no swelling of abdomen nor integuments; harsh mitral murmur and ventricular impulse increased; lungs cleared up; looks well.

October.—No albumen, but liver enlarged, and jaundice; severe dyspnœa, but nights good; treated with hyd. cum creta and nitric acid.

November.—Liver reduced in size, but tender, and full over left lobe; murmur less intense, and heard higher up over sternum; (increased dilatation.)

February, 1873.—Liver natural; repeat infus. digitalis.

April.—Another attack of jaundice, &c., and scanty urine, relieved by digitalis and mercurial purgatives; dyspnœa not complained of; murmur as before.

In July he went to Leicestershire to buy stock, contrary to my advice; got shaken in a rough dog-cart over bad roads; was seized with acute pain over liver; returned to Hertfordshire (his home) with difficulty, and died with effusion in the peritoneum soon after.

This case illustrates many points in cardiac disease. Beginning by pulmonary congestion, followed by mitral regurgitation, the kidney and liver were successively congested, the systemic veins blocked, and universal anasarca and ascites occurred. Yet all this disappeared by the use of digitalis continued over months. His death need not have occurred had he been prudent, and his life might have been indefinitely prolonged.

I had intended to extend this subject further, and to introduce more cases in illustration, as also to quote the opinions of various authorities; but I must draw to a close, as this paper is already longer than I had proposed. It may be well, however, to state, as regards prognosis, that sudden death in chronic valvular disease is rare, and that this contingency need not alarm patients so much as it does. In seventy-nine cases given by Dr. Barclay of fatal valvular disease only two were sudden. Opinions, however, differ as regards the cause, Walshe considering that aortic regurgitation is the most common, and Stokes mitral regurgitation, in which opinion Waters concurs. My own observations concur with Dr. Walshe.

IMPAIRMENT, OR LOSS OF VISION, FROM SPINAL CONCUSSION, OR SHOCK. (a)

By Jabez Hogg,

Surgeon to the Royal Westminster Ophthalmic Hospital, &c.

(*Continued from p. 2.*)

In May he was sufficiently recovered to be removed to the sea-side for change. In November he called upon me, and although his movements were slow, and the dragging of his right leg and foot quite marked, and the tingling sensation of his right hand fingers continued to trouble him, he was looking much better, and had gained flesh. His sight had in the meantime much improved, he could read without glasses; the fundus of the left eye presented a nearly normal appearance. I now learnt that the tram company refused compensation, and that in July he had

(a) A paper read at the Medical Society of London, Nov. 8th 1875.

been visited by two medical gentlemen on behalf of the company, when the electric test was vigorously applied to determine the irritability of the muscles of the extremities, but Mr. B. said, "the other doctors expressed themselves satisfied that his case was a perfectly honest one." They were satisfied that the lesion had probably been meningeal.

On the 20th of January, 1875, rather more than a year after the accident, and in anticipation of judicial proceedings, Mr. Erichsen, Dr. Moxam, and myself saw Mr. B. in consultation. He was, as I have before said, much improved in health. The right arm, hand, leg, and foot were partially paralysed, and some contraction existed about the muscles of the shoulder-joint and leg. On coming downstairs he was obliged to hold firmly by the balustrade and descend step by step; he could not undress without assistance, nor write freely, so that his business aptitude was considerably impaired; was unable to work more than a few hours daily. His eyes remained irritable in a strong light, and produced a contracted state of the brow; the pulse was feeble and compressible, and he suffered from constipation. As the condition of the patient appeared to be almost stationary, the question we were called upon to decide was, "Will the patient completely and entirely recover, so as to be in the same state of health that he enjoyed before the accident." The progress already made, although it demanded a guarded prognosis, seemed to warrant the conclusion that he would in time lose all traces of the injury.

The defence took an unexpected and somewhat remarkable turn. The medical witnesses for the tram company, who, be it remembered, only saw the patient at a distant period of time after the accident, and when he was fairly on the road to recovery, ventured to affirm that the paralysis originated in *syphilis*. The grounds for this extraordinary opinion were that Mr. B. had confessed to some youthful indiscretion, had, some fifteen years before, been treated for a gonorrhœa, and it was assumed and alleged that at this time he must have suffered from syphilitic iritis, which had damaged his eyesight. The fact of the patient having since then become the father of five or six healthy children seemed to have no weight with those who originated this remarkable opinion, and which I am glad to say was rejected and discredited by judge and jury.

The case, as Mr. Erichsen observed, possessed points of interest, and was one not likely to be mistaken for syphilitic paralysis by those who had watched it from the outset. The interest of the case consisted in—1, That the paralysis and spinal symptoms did not begin to show themselves for nearly twenty-four hours after the accident; 2, That there had been no blow or direct injury to the spine; 3, That the symptoms were clearly explicable by Brown-Séquard's experiments on section of the cord; and lastly, the contraction of some of the muscles and the absence of palsy of the sphincters indicating that the lesion was probably meningeal.

On the 22nd of last month (October), Mr. B. called on me. I found him in the same state of health as when we saw him in consultation. He had then, he said, just returned from Hastings, where he had been staying for a month. The right leg and foot still drags in walking, and he suffers from tingling and cramp of the fingers of the right hand; there is also a peculiar appearance of arrested growth of the finger-nails which attracted attention at the trial, and which was said to be indicative of a syphilitic taint; what is still more remarkable is, that he has lost all sexual desire and power.

I have but little to add upon the treatment to be adopted in cases of concussion of the cord or shock to what I have indicated in the narration of the several cases. The value and importance of rest, however, cannot be over-estimated; rest combined with good nursing, good nourishment, and a judicious use of stimulants, with iodide of potassium and bromide of ammonium in increasing doses. To allay local pain, hot fomentations with belladonna, or a few leeches. For the hysterical condition, hysterical spine, which, as a consequence of shock, generally produces an aggravation of symptoms, soothing means and remedies, the bromide of ammonium, chloral hydrate, and tonics. To procure sleep, morphia, chloral, &c.

With active business men enforced rest often produces mental depression, the hypochondriacal or hysterical state. This, I need scarcely say, retards convalescence, and requires tonics, change of air, and society. In spinal anæmia, the atrophic form of spinal disease, the cold douche, or cold bath, with steel, phosphorus, and other tonics should be tried. And for the removal of local paralysis, the galvanic current is an excellent remedy. Under the best directed and most skilful treatment recovery is often long delayed, or the patient may become the victim of some acute form of disease, and after a few years of protracted misery sink exhausted.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

At the meeting on December 11th, Dr. Lombe Atthill, President, in the chair, the adjourned discussion on Dr. T. More Madden's paper, entitled

OBSERVATIONS ON THE HISTORY AND USES OF THE SHORT STRAIGHT FORCEPS AS A TRACTOR, AND THE LONG DOUBLE-CURVED FORCEPS AS A COMPRESSOR AND LEVER,

which was read at the concluding meeting of last session, was resumed.

The President said it would be in the recollection of the members that at the concluding meeting of last session Dr. T. More Madden read a paper on the use of the forceps, both short and long, raising distinctions between them; and the question was considered to be so important that the discussion was adjourned until the present meeting. Since the reading of the paper the members had had the advantage of perusing it in the proceedings of the Society. He thought, however, that it would be well if Dr. More Madden would now state the points on which he was most anxious the discussion should take place.

Dr. More Madden said he thought no point could be of greater importance to the Obstetrical Society than the best manner and proper time to afford assistance in cases of labour in which the natural efforts failed to accomplish the safe delivery of a living child from a living mother. Within the past few years the great object had been much aided by the more frequent and more judicious use of the forceps in those cases that really required its use. But instead of the judicious and timely use of the forceps, he thought that now that instrument was beginning to get into very frequent and untimely use, and it was employed much too frequently in cases in which its assistance might be dispensed with. When the forceps was first introduced into practice by Gifford, it seemed to be forgotten that it was then used as frequently as it was now, and in the very class of cases in which it was now recommended—before the mouth of the womb was fully dilated. In the hands of some practitioners it was used in almost every case of labour they attended. After a time that abuse of the forceps gave rise to a natural reaction against its employment in those cases in which its use was really necessary, and the result of that reaction was, that for many years the forceps was entirely banished from midwifery practice. From the end of last century, from the writings of those who were then distinguished authors upon midwifery, in the time of Denham, Osborne, and the leaders of obstetrical science in those days, the use of the forceps was regarded with horror, and reprobated and spoken of in the strongest possible terms. When the forceps was driven out from practice in that manner, the instrument which took its place was the perforator. After a time sounder views began to prevail again, and the forceps gradually crept into use, and among those who led the van in bringing it into its proper place in midwifery practice was the late Dr. Beatty. From one extreme they appeared to have gone into another extreme—from the extreme of neglect into the extreme of use. The forceps was recommended in almost every case of labour, in head pre-

sentation, and it was recommended before the os was dilated. They all knew it was quite possible even before the occurrence of the usual labour pains, in some instances, where the os was sufficiently dilatable, that the head might be dragged through before the labour was concluded at all. Every one would remember that labour was a slow process, in which the uterine action expelled the body of the child. If this process was suddenly put an end to instead of it being allowed to continue, and they dragged forth the child with a double-curved forceps as soon as labour set in, he thought the consequences need not be dwelt upon. That in some instances the application of the forceps before the full dilatation of the os was necessary was obvious to every one. On the occasion of his reading his paper he endeavoured to call the attention of the Society to two instruments by which he thought the use of the forceps in those cases which really required it might be facilitated. One of those instruments was a very short forceps—for he believed there were two distinct instruments confounded together in the name of forceps—the long double-curved forceps and the short straight forceps. The long double-curved forceps in the second stage of labour required a good deal of operative skill for its safe introduction, and was an instrument which, in hands not very cautious, was capable of doing a great amount of mischief. He believed that in 99 cases out of 100 in which a forceps was required to be used delivery might be effected with the short straight forceps, and that the long double-curved forceps should be used in those exceptional cases in which artificial delivery was required, before the head of the child had naturally passed into the pelvis. Therefore the points on which he was anxious to obtain the opinion of the Society were as to the proper time at which the forceps should be applied during labour, and whether it was a safe practice generally to effect delivery before the dilatation of the os. He would also be very glad to hear any criticisms on the instruments which he submitted to the Society.

Dr. CRANNY said that, comparing Dr. More Madden's with Dr. Barnes' long forceps, they must all perceive that the latter could be used as a very powerful tractor, as well as a compressor and lever. Dr. More Madden had said in his paper that the forceps were used much too frequently now-a-days; but in another place he said that he was quite as ready to use them as any one else, as frequently as most practitioners did in ordinary practice. The only advantage Dr. Madden's short forceps possessed was, that they were light and handy. If they had an instrument that was quite as safe as Dr. Madden's short forceps, and more useful and more efficient—as they had in Dr. Barnes'—there was no necessity for having a second. It mattered little what period the first stage of labour might be. He (Dr. Cranny) thought Dr. Madden's own definition of the first stage of labour was all that occurred up to the time that the os was fully dilated and the membranes ruptured. But there were various definitions of the first stage of labour, and consequently that was an unfortunate phrase for him to use. If Dr. More Madden had said there was no danger before the os uteri was dilated, and that was what the meaning of the paper was to an ordinary reader, he (Dr. Cranny) thought Dr. More Madden would be wrong. He (Dr. Cranny) thought that the credit was due to Dr. Johnston, late Master of the Rotundo Hospital, for having brought his cases forward, in which he showed the dangers that might arise before the os uteri was dilated, and consequently the necessity for operating in those cases. Dr. More Madden himself admitted in another portion of his paper that it would be necessary to use the forceps as soon as the os was dilated sufficiently. Dr. Cranny did not agree with the reader of the paper that the short forceps were safer than any other. He (Dr. Cranny) had seen Dr. More Madden's forceps fail in very efficient hands. He (the speaker) had seen Dr. Madden's instrument slip off the head of the child. An instrument that was likely to slip was anything but a safe one. Dr. Madden would appear to have used Barnes' forceps but once. He (Dr. Cranny) thought if he used them more frequently he would like them better, as they were a very safe and efficient instrument.

Dr. BYRNE did not think Dr. Madden had brought anything very novel before the Society, and the subject had been a good deal dwelt on before. Yet Dr. Madden had brought the matter before them in a very nice form, and he (Dr. Byrne) thought it was no harm that the difficulties of the introduction of such an instrument as the forceps into practice and the dangers to which it was supposed to give rise should be well known before encouraging others to the use of the instrument.

Dr. JOHNSTON said he had not had the pleasure of reading Dr. More Madden's paper, his time had been so much occupied, but as he (Dr. Johnston) had been prominent in urging the application of the forceps, he thought it right to take part in the present discussion. In the first instance, he thought the great point was, as to the circumstances under which the forceps should be employed. Although he was not an advocate of meddlesome midwifery, he insisted upon it, and the more he saw of it the more he urged on his fellow-practitioners to make use of the forceps early, and not to allow their patients to run on worn out by fatigue. Out of 170 cases in which he had used the forceps before the os was fully dilated he had had only 10 deaths arising from various causes, not attributable in any way to the application of the instrument. He looked upon Dr. More Madden's short forceps as a very pretty instrument, but if the head was high up in the pelvis it would be utterly futile to use it. But they had perfect command of Barnes' admirable instrument, even if the head might be above the brim. He would be able to show that in a great number of instances they had been able to deliver the child, and in the majority of cases alive. The instrument that they used at the Rotundo Hospital, Barnes', was 14½ inches, but he found Dr. Madden's tremendous instrument measured 18 inches. He (Dr. Johnston) thought that was perfectly ridiculous as to using the forceps as a lever; they did not use the forceps as a lever except in the last stage of delivery. He must say that, as far as his experience went, he did not see at all the necessity for that long instrument—in fact, as it had been expressed, it looked just like a cephalotribe. Even the curve of that instrument was not appropriate. The straight instrument could be manipulated just as easily as the double-curved one. He always recommended his friends to carry but the one instrument, and Barnes' instrument could be used just as easily as any other. In recommending the early use of the instrument—in the first stage of labour—he warned every practitioner that he must be most cautious in the introduction of the instrument.

The PRESIDENT said there were three points for discussion—first, was the forceps used too frequently at present? next, was the long forceps capable of superseding the perforator or crotch? and last, were the instruments before the Society superior to those in general use, and whether in use before our own time? As far as he could judge, he did think there was a tendency at present to the too frequent use of the forceps in cases in which the woman could very easily, if left a little longer, be delivered by natural efforts. He thought the use of the long double-curved forceps would enable them comparatively frequently to extract a living child with safety to the mother, who in former days would have been sacrificed. That was his opinion. He did not think the instruments exhibited were superior to those at present in use. He thought Dr. Barnes' double-curved forceps would extract the head in any case where it was possible to extract a living child.

Dr. F. T. PORTER wished to ask Dr. More Madden whether he had noticed any remote ill effects accruing to the children in the cases where he had used his forceps, for they exercised strong compressing force on the head of the child.

Dr. KIDD said that before the debate closed he would like to be allowed to make some remarks upon the paper. He thought the paper and the debate were both of great importance. It would be remembered that in an address which he had delivered from the presidential chair he had shown by analysis of the various published reports of the great institution over which the President now presided, that in proportion as the forceps were used frequently in cases of tedious and difficult labour the deaths of both mother and child diminished. He (Dr. Kidd) was, and had always been, an advocate for the early and frequent use of the forceps. He agreed, however, with Dr. More Madden in thinking that they were gliding into the habit of using the forceps more frequently than at all advisable. The great rule in his mind as to the propriety of using the forceps was not to be derived from the amount of time that had elapsed, nor from the position of the child's head. The rule he adopted was, that when he found the pulse rise above 100, if he found the tongue become dry, the patient irritable, and perhaps beginning to vomit—though the latter

was a symptom that he very seldom waited for—then no matter how short the time was that had elapsed, he at once recommended that delivery should be completed. That was the rule he had laid down for himself, and one that, if he had any influence with the students or younger members of the profession, he would advise them to adopt. With regard to the operation of using the forceps in the first stage of labour, it should be confined to cases where the os was very dilatable, and those were cases where the necessity for it would arise, and in cases of hæmorrhage or convulsions. With regard to the advantages of the long double-curved forceps, well Dr. More Madden had laid before the Society a very long forceps, with moderate curve, similar to that introduced by Levret. He (Dr. Kidd) thought the double-curved forceps was to be used only in cases of high operation. In cases of low operation, where the head was on the perinæum and the exit was obstructed by the rigidity of the soft parts and their want of action, any forceps would deliver under these circumstances. But in his humble opinion, the disadvantages attending the use of the long double-curved forceps were greater than any possible advantage. In the first place he believed that it was more difficult to introduce. One had to be very careful which blade of the instrument he took up to introduce first. It did not go in a right line with the handle of the instrument, so that the operator had to have his mind's eye on the point of the instrument instead of being simply satisfied with the direction of the handle. He thought, however, that the whole of the discussion as to the double and single-curved forceps—the importance of it, had been exaggerated. If, after all, a man was accustomed to use one or other instrument, and knew what he was about, and understood the anatomy of the pelvis, and the mechanism of labour, he believed the practitioner might use either instrument safely. He maintained that the straight forceps was a safer and more useful instrument than the other. Mr. Porter had alluded to the fact of compressing the child's head with the very long forceps. Dr. Frazer, Inspector of Lunatic Asylums in Scotland, had made a series of observations upon the cause of idiocy, and he maintained that—whether correctly or incorrectly he (Dr. Kidd) was not prepared to say—one of the most frequent causes of idiocy was proved to arise in cases of labour in which there was difficult parturition.

Dr. M'CLINTOCK said that the subject of the paper was one that had elicited warm and profitable discussion. Dr. Kidd had touched upon a point of great importance, to be kept clearly before them when discussing the question of the proper use of the forceps, and that was the distinction between the high and low operations. With regard to the relative advantages of the long double-curved forceps and the straight, he must say that he concurred very much with the observations that had fallen from Dr. Kidd, though perhaps he (Dr. *M'Clintock*) ought not to offer any opinion on this point, as *he had* never himself used the double-curved forceps. He *had* frequently applied the forceps, but it was the straight instrument he had employed, and he thought it possessed a great advantage over the double-curved one. With regard to the important question as to the frequency of the use of the forceps at the present day, he must say that he thought there was a strong tendency to the too frequent employment of the forceps. He entirely agreed with the remarks Dr. Kidd had made with regard to the indications for the use of the forceps in labour. He also agreed with Dr. Kidd when he stated that it very rarely occurred that any serious symptoms arose before the full dilatation of the os uteri. The forceps should be applied before the os was fully dilated only in extremely rare and exceptional cases, and was not at all to be taken as any example or encouragement for the use of the forceps under such circumstances. There was another point noticed in Dr. More Madden's paper, and that was the use of the forceps as a substitute for the perforator. That brought them to the consideration of the best mode of treating such cases, and of managing and conducting them, and they at once entered into a very vexed question, and one that at the present time in America was exciting a good deal of discussion amongst the ablest obstetricians in that country, and that was the relative advantage in turning the long forceps in cases of narrowing of the pelvis. He did not think that any satisfactory solution of that question had been arrived at. With regard to the instruments introduced to the notice of the Society by Dr. Madden, he (Dr. M'Clintock) must say that he did not think he had introduced any new principle whatsoever in the construction of these instruments. They had just been made on the principle of the instruments that had been in use up to the present time. But he must still pay a very warm tribute to the ingenuity, pains, care, and consideration which Dr. More Madden had bestowed upon the construction of these instruments. The long forceps of Dr. More Madden was one that he (Dr. M'Clintock) certainly would never use himself, and would never consent to see it used upon any female friend of his. He was inclined to agree with the observation which had fallen from one of the speakers, that it did not depend upon the instrument to be used, but on knowing the proper case in which to apply it, and even then it should be in hands properly trained to use the instrument with care, prudence, and gentleness.

On the motion of Dr. CRONYN, seconded by Dr. DENHAM, the conclusion of the debate was postponed, and the Society adjourned.

DUBLIN MEDICAL SOCIETY.

THE second meeting of the present session was held on Wednesday, Dec. 8th, 1875, Dr. GORDON, President of the College of Physicians, in the chair.

UNEXPLAINED PYREXIA.

Dr. JAMES LITTLE related four cases in which for forty days pyrexia existed, although, as far as he could make out, there was no symptom of any local inflammation that was due to any of the acknowledged types of essential fever. In the first case the illness had been going on gradually for a week before the patient's admission to hospital, the symptoms being weakness, chilliness, and loss of appetite. The patient did not complain of any definite form of illness. The tongue was furred, bowels confined, the area of splenic dulness was somewhat increased, and the urine was always low. He thought at first that it was a case of enteric fever, but there was no eruption. Some time after admission to hospital the patient was seized with a violent looseness of the bowels, which lasted some days, after which their previous condition returned gradually. The most marked symptoms were a wish to be let alone, and thirst. In another of the cases the patient suffered more than usual from enlarged glands of the neck. For a month she complained of pain in the right shoulder. Ten days before admission to hospital the pain became worse, and the patient suffered from pain in the limbs and back. The temperature was above the normal until the 30th day, and after that was occasionally higher than 99° in the evening. She lay in the bed in an apathetic state, taking no notice of anything about her. She was sleepy by day and wakeful by night. Her tongue was covered with fur; the breath was foul, and the bowels were disposed to be confined. There were no physical signs of fever. Distinct pyrexia did not continue after the 30th day. In all the cases the patients were obliged to keep their beds from three to four weeks, during which time the temperature of the bodies were higher and the pulse more frequent than in health. All the patients were depressed, apathetic, and very weak, but presented no symptom or physical sign justifying a precise diagnosis. The points of interest in these cases were the presence of pyrexia, the peculiar mental state that was seen in all the cases, and the absence of any sign which justified him classing them among the essential fevers, or cases of local inflammatory action. He was left in the dark as to their character, and he was uneasy as to their result. The ultimate recovery of the patients was strongly in favour of the supposition that no fever existed during the pyrexial period. All the patients were of the lymphatic diathesis, and in all cases the sickness had reference to the lymphatic glands.

Dr. GRIMSHAW thought all the cases described by Dr. Little were cases of enteric fever. Unfortunately he (Dr. Grimshaw) had had an opportunity of examining post-mortem a couple of cases which had very much the history which Dr. Little had detailed. The temperature in Dr. Little's cases pointed to the range belonging to enteric fever. In the two cases he (Dr. Grimshaw) had an opportunity of examining there was no doubt about their being enteric fever. In one case the enteric symptoms were very badly marked indeed during life. The patient had no marked tenderness on pressure, and the spots were absent, but the general characteristic of the disease, range of temperature, &c., made him come to the conclusion that the case was one of enteric fever. The patient died. There was ulceration of the intestines, although most of those ulcerations had healed up, and the cause of the

maintenance of the fever appeared to him to be owing to the continued inflammation of the mesenteric glands. The inflammation of the glands arose in the usual way from the poisoning effect of the ulcerated intestine. He had under his care at the present time a case of this sort. This patient had marked chest symptoms along with the other symptoms of fever. He had all the symptoms of fever except the spots; he had diarrhœa, and tenderness over the abdomen on pressure. He was now convalescent. In the other case there were no spots, no pain on pressure over the abdomen. The bowels were inclined to be confined, and he administered purgative medicines. The patient died in about a month, and they found large ulcers in the mesenteric gland. Those were cases where they would expect to find inflammation in the lymphatic glands. He believed that these were cases of enteric fever. He believed that a comparatively slight attack of enteric fever was sufficient, in persons of the temperament mentioned by Dr. Little, to set up sufficient lymphatic glandular inflammation to continue for some time a fever of a sub-typical character, such as in the cases described by Dr. Little. He (Dr. Grimshaw) always regarded these cases with apprehension, because they were very apt to degenerate into some of the forms of lung disease that eventuated ultimately in phthisis.

The PRESIDENT said he had seen several cases that bore some resemblance to those described in the paper of Dr. Little within the last few months. He (Dr. Gordon) had seen very lately two particularly well-marked cases, and he considered them, as Dr. Grimshaw had said, to be cases of enteric fever, in which nervous symptoms, so to speak, prevailed. One was the case of a man past the middle life who left the hospital on that day, after being nine weeks in fever. He came in with the symptoms described by Dr. Little, of depression, of high temperature towards evening, somewhat lower in the morning, but still much higher than health would permit of. He lay for at least three weeks more or less in a listless state. He had no diarrhœa, very little cough, and at length all his symptoms seemed to culminate in the usual symptoms of well-marked enteric fever. Diarrhœa came on rather suddenly, and he rapidly became weak, and required a very large quantity of stimulants to keep him up. However, he recovered rather rapidly considering the extreme low condition to which he had been reduced. He saw another case to-day of a boy who had fever very much of the same kind. He was described as having been listless, of losing his appetite, and of manifesting a desire to lie down and sleep. He took to his bed at last, and remained there for three weeks without any very prominent symptom beyond refusing food and having a dry tongue, and slight delirium occasionally. There was no diarrhœa in this case until about a week ago, when diarrhœa came on very much of the kind that occurs in enteric fever, without abdominal tenderness and without any eruption, and as in the former case, this seemed to be more or less critical, though since then the patient's other symptoms seem to be improved. At present there was in the Hardwicke Hospital more fever than he had seen for a considerable time. The majority of cases were of a more or less nondescript character. Nevertheless, he considered them all to be more or less of a typhoid character, though almost without exception, for a considerable time at all events, there was very little diarrhœa, and very few of the cases were accompanied by the rose-coloured spots.

Dr. DOYLE inquired whether Dr. Little could trace the origin of the disease to any cases of typhoid fever of a bad type near the cases Dr. Little had described, because that appeared to be the only way to account for some of the symptoms Dr. Little had described.

Dr. DUFFEY remarked that during the five years he was stationed at Malta he saw a very large number of cases of fever, which were always entered in the statistical returns as "common continued fever." Their type was the same as Dr. Little had described—the spots were absent, there was no diarrhœa, the convalescence was very much prolonged, and the prostration subsequently was most severe. In all these cases the main point that led people to believe that that fever was not typhoid was that recovery took place in most instances. He was unfortunate enough to have fatal cases, and in those the lesions were the anatomical ones of typhoid fever. In all the cases the ulceration was in Peyer's patches, and there was great enlargement and congestion of the mesenteric glands.

Dr. J. W. MOORE related that three cases were admitted to the Meath Hospital from a school suffering from fever. One of the cases was no doubt an example of enteric fever, while the less severe ones corresponded with those described by Dr. Little. The origin of the disease was traced to the fact that the school was supplied with milk delivered by a girl who had contracted fever, and who was lying some days ill in the house from which the milk was sent.

Dr. LITTLE, in reply, said he must acknowledge that the idea suggested by Dr. Doyle commended itself to him more than any that had been thrown out, because he (Dr. Little) could hardly believe that these cases were all cases of true enteric fever, unless they used that expression in a sense so vague as to deprive it of very much significance. In the instances he had recorded he could not ascertain that any other member of the family had been attacked with any kind of fever. Generally several members of a household would be attacked, and he should have expected that these were cases of slowly developing enteric fever, and that some other member of the family would exhibit the disease in a more typical and pronounced form. Such, however, had not been his experience. He must acknowledge, however, that in several cases he was able to ascertain that the persons were very much exposed to fæcal impregnation—that they were breathing air that was fæcally impregnated. In one case this was very well marked. One of the patients, a gentleman living in Rathmines, spent his day in an office near a place where he (Dr. Little) ascertained there was fæcal contamination. He thought that though these cases might not be enteric fever, it was some modified form of fever arising from the absorption of fæcal emanations.

Staff-Surgeon A. A. GORE (by permission of the Council) then read a paper on

TYPHOID FEVER IN THE DUBLIN GARRISON.

According to the reader of the paper, the Irish command in former days was unpleasantly notorious for the production of all forms of continued fever, the military records of the 17th and 18th centuries showing that continued fevers, called by Boate the "Irish ague," were very prevalent, but so mixed up with epidemic dysentery that to differentiate between the two was not always easy, as shown by examples quoted by the author. Since then the disease had been frequently epidemic, but was becoming less so, owing to the great improvement which had taken place in the health of the inhabitants during the past twenty or thirty years, although following very much the same course as at certain stations abroad, where during certain years the febrile poison was very fatal and prevalent, while at other times, comparatively speaking, inert. Between the years 1837-46 continued fevers of all kinds accounted for an unusual ratio per 1,000 per annum among the troops in the United Kingdom, of from 51·9 to77·7 admissions, falling, with improved sanitation, to a minimum in 1867, when the admissions varied from 9·0 to 16·6, the ratio in the Dublin garrison alone varying from 19·00 to 30·80, but decreasing and rising on the whole with the decrease and rise in the civil statistics, the ratio per 1,000 of cases of enteric fever rising from ·313 per 1,000 admissions in 1867 to ·900 per 1,000 in 1872, the average percentage of admissions at home being ·108, abroad ·280. The disease in tropical and semi-tropical countries being twice as fatal, owing probably to complications with malarial fevers and other diseases, the author pointed out that a study of the army returns showed that the number of admissions during certain years had been, as in civil life, increased by local outbreaks, many of which were noticed in detail. Typhus was a rare disease among soldiers at home, while simple fever and febricula preponderated largely. The author next alludedto the meteorological causes influencing the production of typhus and typhoid, and to the opinions of Dr. Grimshaw and Dr. Moor, to the surroundings of the barracks, and to the opinions held by many physicians of the identity of cause in the production of fever, quoting from the writings of Dr. Cheyne, Physician-General to the Forces in Ireland, and others; next to the mortality from the various forms of fever as shown in the Registrar-General's returns, which clearly indicated a great preponderance of the febrile poison in 1874, and a decrease in the present year, in which decrease the military returns shared, but that while the increase and decrease in the civil statistics was spread over all the forms of fever, the troops suffered only from typhoid, owing to the fact that the essentials to the production of typhus were altogether absent amongst them, while the defects in the mode of getting rid of the excretions were not infrequent. Dr. Gore next alluded to the varying types of the disease, derived from the same

source, the fact of the disease occurring in the form of a number of small local outbreaks, and of the ultimate results, the symptoms as observed in the wards of the General Hospital, and its various complications, slight or severe bronchial symptoms being present in one-half of those treated. In 13 cases in which the period of incubation was accurately fixed it ranged from 1 to 14 days. The range of temperature was next noticed; the treatment of the older physicians in the Cork Street and Hardwicke Fever Hospitals, which, although largely mixed up with blood-letting, only yielded a mortality of 1 in 11. The more modern or rational treatment of typhoid was now treated of, in which milk diet, beef tea, soda-water, little medicinal interference, and the administration of stimulants as the disease progressed and symptoms of debility appeared, entered largely. The author concluded by showing that fever had been decreasing in Dublin since the commencement of the present year, and that in comparison with former periods the garrison of Dublin was exceptionally healthy; that while the mortality from zymotic diseases in the quarter ending the 1st October was in the ratio of 5 per 1,000 of the population, among the troops, including men, women, and children, it was only 1·70, or about two-thirds less, the same favourable results appearing in the case of typhoid fever.

Dr. Henry Kennedy said there were at least two points which had an important influence on the duration of cases of typhoid fever such as had been described by both the gentlemen who had addressed them that evening—the first was the extent of lesion present. This was known to vary in a very marked way; in some instances it was the very slightest, being just enough to pronounce the case typhoid, whilst in others the lesion present was most extensive, involving not only the lower part of the ilium, but in some instances the cæcum. Neither was it to be forgotten that, in a good many cases the colon was also involved, as shown by Louis and others. In addition to all this, again, the mesenteric glands, when once involved, and this was common, must necessarily keep up the fever, and prolong it far beyond the usual averages. From this point of view, then, it could be easily understood why certain cases of the disease ran out to such a length. But the second point was, if possible, still more likely to prolong the case. Dr. Kennedy had read a paper before the association some time back, in which he had put forward the opinion that the majority of cases of typhoid occurred in persons of a strumous constitution, and the more he saw of the disease the more strongly was he inclined to hold this view. The existence of enlarged cervical glands, with scars on the neck and stains on the cornea, were often to be seen in these cases, whilst the prevalence of a very fine skin was common. But, above all, the nature of the lung affection which so often supervened in the progress of the case was not only like phthisis, but too often ran into it. He could not enter further into the point here. Before sitting down he wished to allude to two modes of practice which had been introduced within the last year. One, by Dr. George Johnson, of London, consisted in merely giving milk during the fever, and this gentleman also states no other treatment is needed. Why cases which would go from bad to worse should be left to themselves Dr. Kennedy had yet to learn, and he thought parties would incur blame who did not make at least an effort to save their patient. The other plan was of German origin, and consisted in the use of cold baths, in order to lower the temperature. It was, in fact, a revival of the plan long since introduced by Currie. To the speaker the plan appeared a very questionable one, and there seemed to be distinct risk in many of the cases where these baths were used. As bearing on this point, he might refer to several cases detailed in the volumes of the Clinical Society of London: rigors, livid extremities, chest affection, death, were, or seemed to be, the direct result of the use of the baths, and when the patients did survive, it seemed to the speaker to be more of an escape than a cure. He would be very slow indeed in using cold in this form.

Dr. Grimshaw said that, according to the last medical report of the Cork Street Fever Hospital (which he wrote), enteric fever had been on the increase as compared with previous years. He did not think Dr. Gore had seen that report. It was quite evident there had been an increase of enteric fever lately, and it was only to be expected that large garrisons such as that in Dublin would share with the civil population in this increase. A great deal had been said with regard to the unhealthiness of the barracks in Dublin, and no doubt there was a certain amount of truth in these statements. He did not think, however, that there was evidence to show that the troops in Dublin were more unhealthy than those of other garrisons, where the death-rate was so high in almost any other town in England. According to Dr. Burke's return, the death-rate in Dublin had been 30 per 1000 of the population, and the state of health of Dublin was low.

Dr. Gore said that, as a rule, medical officers used very little medicine in the treatment of the disease, and, as Sir Dominic Corrigan had said, they tried to guide it to a successful course. The returns showed that the garrison was no worse off than the civil population, so far as health was concerned. He thought, too, that Dublin was often credited with cases of fever which had occurred elsewhere. Quinine had always been found to be hurtful to the patients; but castor-oil was very effective where there were any febrile symptoms during convalescence, and generally brought away some hardened fæces. When the tide rose it drove the noxious gases up through the city, and several cases had been proved as arising from that cause.

On the motion of Dr. Henry Kennedy, seconded by Dr. Grimshaw, a vote of thanks was unanimously passed to Dr. Gore for his valuable paper.

The Society then adjourned.

WEDNESDAY, JANUARY 12, 1876.

THE SANITARY CONDITION OF INDIA.

Our Indian dependencies at this moment are centres of great attraction, for Englishmen especially, and every telegram is eagerly and carefully scanned, for all are anxious to know whether the Prince's progress will be barred by that scourge of the East, the cholera. An unusual outbreak just now is, we hear, regarded as little short of a national calamity for India, since it is feared that, after all, the greater part of the people will not be gratified by a sight of the Shahnadah. Dr. Fayrer only discharges his duty by putting the Presidency of Madras under ban; had he acted otherwise, a great outcry would have been raised, as we cannot afford to have the Prince's life placed in the slightest danger, even should Ramo Samsee appear in sackcloth and ashes, and the Aryan weep for disappointment. It is said, why make all this fuss, as the cholera has only appeared in its well-known sporadic form, and so prevalent in all Eastern cities at certain periods of the year? To this we say, Dr. Fayrer's

great experience must be trusted ; he knows so well how far we may trust the disease and what is likely to be the consequences of bringing together the vast hordes and camp followers of Rajahs ; that even sporadic cholera may show itself at any moment in its most virulent form. So far the Government have been on the alert, and from the greater interest shown in sanitary science of late, we may rest assured that every possible precaution will have been taken to avoid a shadow of a risk.

We have very recently received a valuable report on the sanitary condition of India, showing what has been done and will be done to secure the health of the vast mixed populations of the country. Amongst other important matters, we find that the Commissioners, Drs. Lewis and Cunningham, have continued their special and valuable investigations into the nature and cause of cholera, and which has added, as they assure us, to a former strongly expressed opinion that the disease is not contagious; that it is infectious seems to be doubtful; and the result at which they have arrived is apparently that the prevalence of the disease is intimately connected with meteorological phenomena, though of the nature of the connection nothing at present is known. Dr. Cunningham is convinced that cholera is due to certain conditions of air and soil which are as yet but little understood. The conclusions arrived at are so far only negative. The subversion of the popular opinion regarding the causes of fever seems to be on a par with that of the general ideas as to the origin of cholera. While, in Bengal and Madras, it is attributed to the undue raising of the water-level and the stagnation of the subsoil water, in the Punjab malarious diseases appear where the subsoil is in a state of extraordinary dryness. Dr. Evers has made a valuable discovery, should his experiments be confirmed on further trial, that the bark of the well-known Champa (*Michelia Champaca*) is efficacious as a substitute for quinine as a tonic and febrifuge. There has been an opinion that the natives of India enjoyed an exemption from typhoid fever, but the experience of 1873 shows this to be incorrect. The rarity of the disease among adults, it is suggested, may be due to the majority of them having passed through it during infancy, children suffering to an enormous extent, while little or nothing is known of the exact nature of the diseases which attack them. Small-pox seems to be as capricious in its character as cholera and fever, leaving some villages intact, while others suffer severely, showing that contagion is not the only agency by which it is spread, and that, notwithstanding its contagious character and independently of the influence of vaccination, a district may escape, though apparently exposed to the full virulence of the disease. Some light has been thrown upon the loathsome malady leprosy by the researches of Dr. Carter. It seems to be proved that it is not contagious, but that it is, in almost all cases, transmitted by hereditary descent, bad and innutrious food causing or hastening its development. Good, nutritious aliment always tends to retard the progress of the disorder, but little is known of any cure for it. Surgeon-Major Dougall reports extraordinary results from the use of gurjun oil (*Dipterocarpus lævis*), but he cannot yet speak as to the permanency of the benefits of the treatment. Chaulmogra oil has been tried at the Jamsetjee Jeejeebhoy Hospital in Bombay, and has given satisfaction. The obstinate ulcers known as Delhi sores appear to have at last received a check. It has long been known that the want of drainage in the basin of that city was the cause of this disease, and improvement in this respect has resulted in a great diminution of the malady in the last few years.

We learn also some interesting facts with regard to vaccination. Notwithstanding the objections frequently raised that the performance of this operation would meet with an insuperable obstacle in the religious prejudices of the natives, it appears that when once they can be persuaded that it is to their interest to submit to it, all notions of injury to caste are thrown to the winds. In Madras, hundreds of men, women, and children hastened to be vaccinated, the Government having sanctioned the payment of a reward of two annas, or 3d., to every person undergoing the operation. A thorough fright, or perhaps it would be more just to say a striking proof of the efficacy of vaccination, was attended with no less satisfactory results. At a village in Berar the putwaree refused to allow his child to be vaccinated, but sixty other children were successfully operated on. In the hot weather of 1873, epidemic small-pox having broken out with considerable malignity, the putwaree's child died, but the whole of the sixty children who were protected escaped. Consequently, in the next season, when the vaccinator appeared in the village, all the mothers crowded round him with their infants, and two women who happened to be absent at the time followed him for ten miles to another village where he was engaged, in order to have their children operated upon. It is curious that even the superstitious Mussulmans seem to have a greater objection to vaccination than Hindoos. The facts given above, however, tend to show that in reality there is nothing in the operation in any way offensive to caste.

Fearful as are the ravages of cholera and small-pox, still the deaths from these causes are counted only by tens of thousands, while fevers slay their hundreds of thousands. This is hardly to be wondered at when we read the accounts of the sanitary state of many of the villages, especially in the eastern districts of the Bengal Presidency. Partly dried watercourses, marshy rice-fields, stagnant ponds overgrown with weeds, and pestilent with decaying organic matter, garnished with a broad fringe of variegated mud trampled by cattle, every hoof-mark containing concentrated essence of malaria in its direst form —these are the places where the people perform their ablutions, the washermen wash their clothes, the buffaloes seek refuge from the sultry heats of summer, and all the water, whether for drinking or for culinary purposes, is sought.

THE LYMPHATICS OF THE LUNG AND TUBERCULOSIS.

Of all the diseases that afflict the human race, tubercular consumption is one in the true nature and treatment of which we cannot fail to be most interested. Of all diseases, phthisis is perhaps the one most dreaded by the family circle. It is a disease with which we daily grapple, and over which we rarely obtain a complete mastery. The

large mortality arising from it, especially in this country, the obscurity in which its pathology has been involved, and, in most cases, the futility of all medical treatment, are circumstances which invest it with more than usual interest, and which should make us hail with the greatest pleasure any discoveries that tend to enlarge our knowledge of its pathology and treatment. It is only within a recent period that phthisis has ceased to be one of the *opprobria medicinæ*. When some supercilious cynic wished to disparage modern medicine, and to show what *little* advancement we have made, he pointed to this disease as one of which we knew little more than was known in the days of Hippocrates. But there is at last some hope that the cloud which has so long darkened our understanding will soon be dispersed, and that the nature and treatment of tubercle will be ere long as well understood as the nature and treatment of a common phlegmon.

We need scarcely remind the reader that until very recently tubercle was regarded as a specific non-inflammatory deposit. The general opinion was that it was "effused" from the capillaries of the part in which it was deposited, that frequently considerable areas of the lung were "infiltrated" with this product, that under the microscope it presented no regular structure, being merely made up of minute granular matter, irregular corpuscles, nuclei mixed with a variable quantity of fibrin, that it increased in ize by aggregation from without of the tubercular molecules, that it passed through a regular succession of changes, being first grey and semi-transparent, afterwards opaque, and finally soft and cheesy, that the softening and disintegration of this deposit was frequently owing to its acting as a foreign body, and exciting in the surrounding tissues a fluid secretion, which mechanically divided or broke down the tubercle, and finally, that this tubercular matter was always an essential constituent of pulmonary phthisis.

Undoubtedly the first and most telling blow that was given to the old theories was when Buhl, eighteen years ago, showed that in many cases of acute tuberculosis there were caseous or cheesy masses in some part of the body, and that from these masses substances were absorbed which infected the whole system, and led to the development of tubercles in other parts of the body. These views have received strong support from the more recent experimental investigations of Villemin, Burdon-Sanderson, Wilson Fox, Hering, and others, who have also shown that deposits closely resembling, if not identical with, tubercle, and which had a marked tendency to become cheesy at their centres, might be developed not from caseous masses only, but from various inflammatory processes, the products of which entering the circulation or the absorbents, gave rise to the secondary deposits. Acute tuberculosis, or miliary tubercles, is, therefore, an infective disease, characterised by the dissemination of minute nodular growths in various organs and tissues. These nodules or granulations are due to inflammatory irritation set up in the infected tissue by the particles that have been taken up by the circulation from the primary inflammatory lesion; so that the disease is, as respects both its general and local manifestations, a sort of pyæmia, with this difference only, that whereas in pyæmia the local inflammatory action depends upon much more violent local irritation, and is remarkably acute and severe, in tuberculosis it is as remarkably slight, chronic, and of limited extent. Nor is the microscopical appearance of tubercle so structureless as was formerly supposed. On the contrary, it is now said to present very uniform appearances, and such as to indicate its mode of origin. For either it consists of adenoid tissue, *i.e.*, a tissue chiefly made up of lymphoid cells, alone, or within the meshes of a fibrillated or nucleated reticulum—or, as in the lungs, of accumulations of the endothelial cells which line the alveoli. In some cases we have a combination of these structures, while in connection with both of them there are those peculiar giant or large multinuclear cells which have excited so much interest among histologists. But, be it adenoid tissue or endothelial accumulations, the origin of the lesion is the same—a peculiar form of local inflammation excited by a *materies morbi* derived from a primary focus of infection.

Now the chief interest that attaches to the recent researches of Dr. Klein, of which we have lately given a detailed review, consists in their bearings upon the subject now under consideration, and in the views which this observer holds with respect to the nature of both artificial and natural tuberculosis. As the adenoid tissue, which plays so important a part in tubercular structures, is always found in connection with lymphatic vessels or glands, it follows that the more we know respecting the anatomy of those vessels the clearer will our notions be respecting the share they take in the formation or dissemination of the tubercular matter. That the lungs were, like other parts of the body, richly furnished with lymphatics, was a fact well known to anatomists. But the free communication between the different portions of those vessels, the manner in which the blood-vessels are often completely surrounded either with lymphatics or lymph spaces, the situation of the lymph-follicles, and the very interesting points in connection with the *stomata* and *pseudostomata*, are facts with which, previous to the researches of Dr. Klein, we were not so well acquainted.

The value of Klein's researches consists in the greater precision they give to our knowledge, or, to speak more cautiously, our ideas of the morbid lesions which are observed in both natural and artificial tuberculosis, and also in the strong corroboration they afford of the opinions and observations of previous investigators. With respect to *artificial tuberculosis*, Dr. Klein endeavours to show that the lymphatics themselves are very much involved in the production of that disease; that the majority of the miliary granulations are actually due to the conversion of those vessels (and the tissue surrounding them) into "cords" of adenoid tissue; that another kind of semi-transparent granulation is due to a hyperplastic state of the peribronchial lymph-follicles; that a third kind owes its origin to a form of catarrhal pneumonia; and that only the latter kind undergoes the cheesy transformation. It is also his opinion that most of the lymphoid cells, both of the lymphatics in a state of health, and of the perivascular lymphatic cords, are emigrated colourless blood-corpuscles. With regard to *acute tuberculosis in man*, the views of Dr. Klein do not appear to differ much from those of Buhl, Hering, and other observers. For the general opinion of these microscopists seems to be that the natural disease is for the most part due to a form of desquamative or catarrhal pneumonia, the chief difference of opinion

being with respect to the nature and origin of the multinuclear or giant cells.

Now it is impossible in a short article to notice this subject in such a manner as it deserves, but we cannot help remarking that even many years ago observations and opinions were published which plainly foreshadowed those more recent doctrines of which we have just given a brief outline. Even Buhl was not the first to demonstrate the possibility of producing tubercle artificially, inasmuch as M. Cruveilhier long ago performed similar experiments to those of Buhl, and by injecting fluid mercury into the veins of dogs, produced in their lungs nodules resembling miliary tubercules, from which he drew the conclusion that these bodies are formed in consequence of a stasis of the fluid in the capillaries, followed by a morbid secretion. Nor is the inflammatory doctrine of tubercle one that has never occurred to the minds of the older pathologists. Broussais went so far as to say he had never seen tubercles in the lungs without antecedent inflammation; and Dr. Alison, in some papers published in 1820 and 1830, concluded that tubercles may be, and often are, deposited in consequence of inflammatory action, and thought that actual pulmonary phthisis might frequently be prevented by the early and prudent use of antiphlogistic remedies. It must, however, be allowed that the older writers used the term "inflammation" in a much more restricted sense than we now do; and, therefore, if the inflammatory doctrine of tuberculosis and pulmonary phthisis could in those days find some supporters, it is much more tenable now that the inflammatory process is regarded as a perversion of nutrition, and now that it embraces minute textural changes that would formerly have been totally disregarded or would have been attributed to other pathological causes, and called by another name. But although, owing partly to this modern acceptation of the term inflammation, and partly to improved methods of microscopical research, our knowledge of the subject has made considerable progress, we are scarcely justified in altogether ignoring the opinions of our predecessors, while we almost regard our recent discoveries and doctrines as final and exhaustive, and such as are not likely to be set aside by future investigations. We say this because we find that there is a great tendency to regard the infective nature of human tuberculosis, and the inflammatory nature of the local lesion as, in the words of Bacon, "sure and measured truths," and to serve them up in our text-books as amongst the most settled points in pathology. This is hardly justifiable, considering that there are many important points on which the best observers are not agreed, and on which much more light has to be thrown before we can be sure that the infective origin of tubercle and its inflammatory nature are well established facts beyond all future cavil and dispute. Quite recently Dr. Metzquer has read before the Academy of Medicine of Paris the results of numerous experiments, from which he has inferred the non-inoculability of tubercular matter, and his papers have been considered of sufficient importance to induce the Academy to appoint a committee of investigation on the subject, comprising Messrs. Villemin, Hérard, Guérin, and other eminent observers. And then with regard to the histological characters of tubercle, if the difference of opinion which characterised the descriptions given by Constatt, Vogel, Gerber, Lebert, and others, discredited the views which they held respecting the structure of tubercular matter, we cannot say that the observations of recent investigators are entirely free from the same objection. Dr. Klein has himself drawn our attention to the important differences which exist between the assertions that Drs. Sanderson and Fox have respectively made with regard to the nature of the granulations in artificial tuberculosis; while with respect to acute tuberculosis in man, we have seen, in the review of his work, that there are certain important points in which Dr. Klein ventures to differ materially from Buhl and Hering. Even in reference to the origin and nature of the much-talked-of giant cells there is great difference of opinion, while Hering goes so far as to say that they are not cells at all, but "correspond most probably to lymphatic vessels cut transversely!"

But with these reservations, which we think it right to make, we have not the least hesitation in saying that the progress which has been recently made in our knowledge of this intricate subject is solid and lasting. The very act that pulmonary phthisis has been shown to be often due to certain forms of the inflammatory process, instead of to some specific and ill-understood exudation or deposit, is not only more hopeful in a therapeutic point of view, but is alone sufficient to call forth our admiration and our due acknowledgment of the great labour and research which have been devoted to the solution of one of the most difficult problems in pathology.

THE CERTIFICATE SYSTEM IN DUBLIN.

The resolution of the Board of Trinity College, adopted after an interview with the deputation of hospital surgeons and teachers, ordered, it will be recollected, that for the degrees of the University of Dublin no certificate should be received which did not guarantee the attendance of the student on a certain minimum number of lectures or hospital visits, and it furthermore provided that those attendances should be testified by means of tickets filled up by the student and handed to the teacher at each lecture or visit. These tickets are simply slips of paper endorsed respectively "Hospital Lectures," and "Clinical Instruction," and bearing on the face the name of the student and the tutor and the date.

As regards hospital instruction in Dublin, the question of attendance may be said to be thus settled as far as the University of Dublin can settle it, and, as regards Trinity College students, it may be assumed that the ready method of wholesale certifying without any knowledge of the attendance of the student, and even the system of entering names in a book (in which one student could write in a dozen names if he liked), are finally disposed of. A more serious aspect of the same subject has, however, to be faced when the certificate system of school lecturers comes to be dealt with, and we hear that that question has already been opened to its fullest extent by the Medical Registrar of Trinity College by the rejection of a certificate from one of the leading schools in Dublin because it did not state the number of attendances of the student, and we understand that the student in question has ap-

plied to the governing body of the school for a refund of his fee, or for other satisfaction, on the ground that the school had contracted with him that its certificates would be recognised by all licensing bodies, a contract which it has now failed to fulfil.

It is obvious that the University of Dublin has not taken the important step of rejecting one certificate without having contemplated the application of the same rule to all lectures the attendance on which cannot be guaranteed by the lecturer, and the refusal of this certificate may therefore be taken as a public repudiation of all certificates, past or future, which cannot be so verified by the teacher, an act the influence of which on the teaching of medicine and surgery in Ireland cannot be anticipated—the significance of which as a declaration of no confidence in the present certificate system cannot be over estimated. The University of Dublin has, in fact, set a torch to the funereal pyre of the over-lecturing and over-grinding organisation of medical education in Ireland, and the Board of Trinity College has done more by a bold stroke of the pen towards the equalisation of curricula and the reform of methods of instruction and examination than all the declamation of the Medical Council and all the energy of the Conjoint Examination Conference have been able to effect.

It is manifest that every licensing body in Ireland, and in a minor degree those in England and Scotland, are placed face to face with the necessity for accepting or repudiating this action of the University, and will be obliged to consider how far they can continue to receive the certificates which Trinity College has dishonoured, and what may be the influence of their doing so upon the professional standard of their diplomas and degrees. They may say, perhaps, that they consider the fastidiousness of the University of Dublin to be unjustified by any shortcomings in the existent system, which, though not perfect, is capable of offering fair testimony to the diligence of a student, and they may, therefore, continue to accept the discredited certificates. But this self-satisfaction on the part of any licensing body will not prevent the public and the profession attaching a high degree of value to the degrees of a body which declares that it will give its *imprimatur* to none but those whom it knows to be industrious and well educated, and, should any licensing body find it necessary to admit that it does not attach as much importance to diligence and personal observation as the University does, it must inevitably consent to take in Irish medical education that lower position which it has never yet admitted that its diplomas occupied.

Of the three Irish licensing bodies who are involved in the consideration of this question the Royal College of Surgeons is evidently that whose policy and interests are most seriously compromised. The Queen's University has never been excessively exigeant about lectures or hospital attendance, having rather inferred, by the nature of its curriculum, that it attaches very little importance to such evidence of proficiency, but depends mainly upon its examinations for proof of professional competency in its graduates. Moreover, its interchange of students with the University of Dublin is absolutely *nil*, so that anything which the board of Trinity College may say or do can have nothing but an indirect moral effect upon it. It thus appears that the Queen's University may continue to receive *nulla-fide* certificates without any serious infraction of its policy or any serious lowering of its dignity below what it now is.

The College of Physicians has a deeper interest in the matter, being moved by a praiseworthy ambition to keep its licence as nearly up to the level of the M.D. of the University of Dublin as is possible, and having a considerable interchange of graduates with the University. Moreover, it is the patron of several of the professorial chairs in the School of Physic, and has been, of late years, closely allied with the Trinity College in its policy, and for these reasons we anticipate that—if it feels itself called upon to declare its intentions on the subject—the College of Physicians may probably follow the example of the University and insist on *bonâ-fide* certificates.

The College of Surgeons is in a different and far more difficult position, inasmuch as it cannot consider the question without serious regard to the interests of its own school, and of the private schools whose guardian it once was. It is, moreover, the licensing body whose relations are closest with these schools, and whose interchanges of students with the University are most numerous, and the course which it adopted towards the Irish Conjoint Examination Scheme shows that its acts are dictated by an overwhelming majority of teachers and grinders who, no doubt, will be as unwilling to submit to enforced roll-calls (and the direct consequences of them) as they were to a conjoint examination which would have involved a clipping of the lecture curriculum.

The University itself will be seriously influenced by the movement, and we shall—on another occasion—endeavour to analyse its effects upon its originators.

We are unable to pursue the subject further to-day than to express the earnest hope that the governing authorities of the three Irish licensing bodies will approach the consideration of these matters in an earnest effort to look beyond the petty interests of individuals, and forward the inevitable reform in medical education towards which the public and the profession have steadily pointed the finger for some years. We believe ourselves authorised to assure the Senators, Fellows, or Councillors who will have to decide the policy of these licensing bodies, that no effort of theirs will bring to a stand the irresistible change to which the University of Dublin has given a first impetus, and that any unreasoning attempt to sustain abuses or protect personal interests which are not protected by right or common sense can only impede the progress of medico-educational reform for a year or two, and will inevitably place their *protégés* in a worse position (as such efforts have already done) than they would otherwise occupy. A fair and honest settlement of the questions at issue—without changes revulsive or prejudicial to the just rights of teachers—is not only possible, but easy; but such a settlement cannot be attained by obstinate resistance to principles which everyone knows to be fair and just, or to reforms which everyone feels must come before long.

THE WATER SUPPLY OF LONDON.

THE water supply of towns is exciting alarm on all sides, and it is quite apparent that the Legislature in the forthcoming session of Parliament must grapple with the crying evil, and offer the metropolis a remedy. The revelations of the Rivers Pollution Commission prove without doubt that the water supplied to the greater part of London, notwithstanding the increasing care of the water companies, contains a large amount of sewage. So much danger is apprehended that some of the parochial authorities of the southern and western districts in the simplicity of their hearts have issued an appeal to householders to look to their cisterns, as if looking to cisterns would keep out the disgusting contaminations sent into them through the mains of the water companies. Householders can exercise no control whatever over the quality of the water sent into their cisterns. Can parochial authorities suppose that dangerously-polluted water can be rendered wholesome and fit for domestic uses by any amount of house filtration? If they do they are utterly mistaken. A constant water or meter supply, much spoken of as a cure for many evils, certainly must in the present state of the Thames rather tend to increase than diminish the danger to health. Nothing but a complete change of system will be of the slightest benefit, for, as Lord Camperdown pointed out in a letter to a morning contemporary, scientific authorities, after a long, patient, and exhaustive investigation, have shown "that the water supplied to London for domestic purposes is thoroughly unfit for use. The assertion is based upon a series of careful analyses and examinations, the report of which every person should study for himself. The information is no new revelation; but perhaps the authoritative refutation of an oft-told tale may at length arouse the attention of the public. I would strongly urge the water consumers and ratepayers of London to read the report itself, and then consider whether it is not time to follow the example of some large towns, and introduce water from some purer source."

The Royal Commissioners are decidedly of opinion that the rivers Thames and Lea should be abandoned as sources of water supply—a recommendation which we have made again and again, and which has received the support of the medical profession, and of many eminent engineers who have studied the question, for subsidence and filtration will not convert the sewage sent into these rivers by the hundred thousand of inhabitants resident on their banks into pure and wholesome water. Nature, however, has stored up an abundance of water, and which can be easily procured, as has been done by the Kent Water Company. Most of the water from deep wells and springs can be easily and cheaply softened on the large scale by the process known as Clarke's process; and thus the sanitary authorities of towns have at their disposal a method of rendering hard water soft and available for all purposes without diminishing its palatableness or its wholesomeness. The method involves the use of lime, but the came effect can be achieved by carbonate of soda, or even by boiling.

"Granted the necessity of seeking new sources of water supply, is the task to be committed to the present private water companies, or is it to be entrusted to some public body?

"Very little reflection will show that private water companies are not the agency by which such a change can best be carried out in the interests of the public. A private water company naturally regards the public as an aggregation of water consumers, certainly, but first of dividend payers.

"Again, the credit of a private water company cannot be so good as the credit of a municipality or other public body, based upon the security of the rates; and, moreover, any new scheme would, if entrusted to a private company, be an occasion for the creation of fresh share capital—a system of raising money which inures directly to the advantage of the shareholders and to the disadvantage of the public.

"The experience of most of the large towns in England is in favour of placing the control of gas and water in the hands of the municipalities; and there is no reason why what is true in the case of other large towns should not be true also in the metropolis, even though labouring under the disadvantage of having no central governing authority.

"It is, at all events, to be hoped that Parliament will, in conformity with the advice of the Commissioners, refuse to sanction any further Bills which may be promoted by the water companies, involving new schemes and expense for filtration, storage, &c., of a supply which must ultimately, even if not immediately, be given up."

Notes on Current Topics.

The Medical Defence Association.

THIS Association is well worthy of the sympathy of the medical profession at this juncture. There can be no doubt that of late years, and notably in the metropolis, it has become more and more difficult for a practitioner of medicine to live solely on the rewards of his profession, owing to the immense amount of charitable aid granted by members of the profession to persons perfectly able to pay for advice. In addition to this, there are at present a host of pretenders to diplomas in medicine who do much to degrade the practice of the art. At a general meeting of the members of the Medical Defence Association, held at the Guildhall Tavern, Gresham Street, on the 21st ult., Dr. Richardson, F.R.S., in the chair, as President, the following additional Vice-Presidents were elected for the ensuing year—Dr. Herbert Davies (Treasurer), Dr. E. Sansom, Dr. White, and Mr. Spencer Watson. The following gentlemen were elected members of Council, viz.—Dr. Allen, Mr. Aubin, Mr. Brooks, Mr. Carpenter, Mr. T. Cooke, Dr. Cuolahan, Mr. Drew, Mr. S. Gardner, Mr. D. Hemming, Dr. W. Johnson, Dr. P. Leslie, Mr. N. Maclean, Mr. W. Mason, Mr. M. Reid, Dr. C. Royston, Dr. J. Slater, Mr. W. Smith, Dr. J. Stevenson, Mr. D. Thomas, Mr. D. Turner. We wish the Association all success.

The Advantages of Reproductive Industry in Lunatic Asylums.

CONNECTED with the question of expenditure, the Irish lunatic asylum inspectors refer in their last report to this subject. On the first establishment of these institutions, nine in number, by a special Board of Commissioners, the quantity of land attached to them in the

aggregate was only 120 acres, a very limited allowance indeed in a country where in the absence of manufactures means for agricultural employment ought to have been fairly provided. Since the appointment of the present inspectors to office, and particularly after being nominated in 1858 Joint Commissioners of Control, they have continued to urge the advantages derivable from increasing the extent of those that appear too limited.

Up to the year 1845 the total land belonging to the twelve district asylums then occupied did not exceed 116 acres, at present to 22 of these institutions 836 acres are attached. The value of produce sold in 1874 was £2,790, and of produce consumed £7,840, a net profit resulted at the rate of nearly £8 per acre. It is clear from the preceding statement that with an ample extent of land for grazing and cultivation, two important objects are attained—employment aud economy. In a sanitary point of view, whether as regards an ultimate restoration of mind, or tranquillity of conduct, no curative agent, or any scientfic treatment is more calculated, in our estimation, to benefit the insane than out-door employment and exercise in open unprison-like grounds.

Scarlet Fever.

In consequence of an outbreak of scarlatina at Epsom College in July last, the boys were sent to their homes before the end of term. Last week Dr. Hardwicke held two inquests at the Nottingham Arms, Marylebone Road, on persons whose death was due to suppressed scarlet fever. It appears that a boy, æt. 4, living at 83 Cleveland Street, Fitzroy Square, was left in the sole charge of his sister, a girl of eleven, on account of the mother having gone away. The children suffered much from neglect, and were very dirty. Dr. Spurgeon, of Henrietta Street, Manchester Square, as the result of post-mortem examination, said the death was due to suppressed scarlatina, accelerated by the gross neglect on the part of the parents. Two children in the family had died of the disease within three months. The second inquest was as to the death of *Frederick Boylin*, æt. 7, of 2 Little York Place, Baker Street, who was out playing in the street on Wednesday, and died the following evening. Up to Wednesday the boy was at school during the day, notwithstanding that a younger brother was ill of scarlet fever at the time. Dr. Thomas, on being called in, ordered the boy to be taken to the Fever Hospital, but the parents refused. He therefore said he could not come again. The deceased was taken ill on Wednesday on coming from school; convulsions set in, and he died. The parents had lost two children out of six, and two are now suffering from the fever. Dr. Dowd, of Lisson Grove, certified that the death of the deceased was from suppressed scarlet fever. The Coroner censured the mother for sending the deceased to a large school whilst another member of the family was ill. The parents lived in a front kitchen with the family, and paid three shillings weekly for rent.

Committal of Lunatics by Magistrates in Ireland.

The inspectors of Irish lunatic asylums give expression to a very strong representation on this subject in their last report. "In former reports," they say, "we adverted the inconsiderate manner, to use a mild term, in which magistrates committed lunatics to asylums as dangerous, in many instances not taking the trouble to make proper inquiry into the merits of the case, in others acting without a due regard to the provisions of the statutes, clear and definite in themselves; thus they injudiciously supersede the functions of the governors of asylums, entail occasionally an uncalled-for county expenditure, and give a continued trouble to the executive, obliged for law sake to rectify their errors, in fact to keep them out of harm's way, and a liability to civil actions for illegal confinements of the subject. The evil is certainly being abated through the intervention of circulars to justices directly from Government with a strict injunction to committing magistrates to secure to the reputed insane transferred by them to asylum under warrrnt, every care and attention during their conveyance, instances having occurred of females being sent from forty to fifty miles alone and under armed escorts, and of men being manacled by locks and tied with ropes in the conveyance."

A reference to the statistics of admission shows that of the 2,154 new patients admitted to district asylums, no less than 1,100 were committed as dangerous by justices, some little beyond childhood, others in the last stages of debility or senility, who barely reached their destination in time for death.

Dr. Richardson on Alcohol in Therapeutics.

Dr. Richardson remarks that in cases of debility with dyspepsia, his experience is that such symptoms are nearly in every instance caused by alcohol, and that total abstinence is the only certain remedy. The phenomena thus described are the symptoms of alcohol when taken in what is commonly presumed to be a moderate, and as it has seemed to many, a necessary quantity.

As to the administration of alcohol in large doses in hæmorrhages, Dr. Richardson has come to the conclusion that this practice is quite erroneous, and he now uses warm milk instead of alcoholic fluid in cases of sudden loss of blood. "The teachings of Dr. Todd led many practitioners to rely, as they expressed it, on alcohol, to the exclusion, in some instances, of all other active treatment. For my part, I was never drawn into the practice of the extreme school; but for more than twenty years I held by those lessons which I originally learnt from my first masters. Within the past six or seven years a change has come over the medical world in respect to the value of alcohol as a remedy. This change is due to the new light that has been thrown upon the subject of the physiological action of alcohol. I do not now enter on the physiological question. It is sufficient for me to say that, without any kind of prejudice against alcohol as a remedy, with indeed some prejudices in its favour, I have felt it a duty to study its medicinal action in a more critical spirit than I did originally, and that the result is a correction of many errors of grave import."

Army Medical Reports.

The Blue-Book of the Army Medical Department for the year 1873 has just been published. The Appendix

includes several contributions and papers which are of quite recent date.

Contagious Diseases Acts.—The report contains a statistical *résumé* as to the amount of contagious venereal diseases at the military stations from the year 1860 up to 1874. These statistics would seem to show a very great decrease of venereal disease at the stations under the Acts as compared with those not under them.

Enteric fever had been very prevalent among the troops in India in 1873.

Report on Hygiene.—Dr. Parkes contributes a paper on this interesting topic, which is followed by another on the Ashantee campaign; after which there come two papers by Dr. Fleming, one on the examination of the drinking-water of Cape Coast Castle, and another on the fatal cases in the Ashantee War. Surgeon-Major Porter gives a paper on aneurism from gun-shot wounds; on psoas and lumbar abscess; on foreign substances in the œsophagus; with a paper on that interesting and important debate about chloroform and ether which is now going on. There are two articles on enteric fever by Surgeon Page and Surgeon-Major Gore, an account of Bangalore by Surgeon E. Nicholson, some notice of the Andaman Islands by Surgeon Douglas, and several other interesting contributions.

Sudden Death after Injection of Iron in Post-partum Hæmorrhage.

Dr. Cederskiöld reports a case where a woman, after the birth of her second child, was seized with flooding. The uterus did not contract fully, and its fundus could be felt over the pubes. Ergot was tried without avail, and the bleeding recurred from time to time. Eighteen days later a solution of perchloride of iron, one part in seven, was injected into the uterus. When the injection was half completed the woman complained of pain, and, after a few breaths, died. On making an autopsy next day, it was found that the small intestines were congested. The peritoneum in the neighbourhood of the fossa of Douglas was found studded with black spots. The uterus was rather firmly contracted, and its interior stained dark brown. It was uneven, and covered with reddish granulative tissue. Three superficial oval ulcerating surfaces were found from one to two inches long at the fundus and sides. Here the substance of the uterus was exposed, and had a ragged surface, where open-mouthed vessels were seen, some of them large enough to admit a fine sound, and which passed into the veins of the uterus. These were followed up into the hypogastric veins. Bubbles of air were seen in these and in the right side of the heart.—*Swedish Med. Society.*

The College of Surgeons of England.

The College of Surgeons has now established a separate Board of Examiners. This is a very important fact to chronicle, since the College of Surgeons is still the great Licensing Board for England. On the 6th of November last it was stated in an advertisement that the Board of Examiners would consist of nine members, to be elected from the Fellows of the College. In reply to this, twenty-eight gentlemen applied for the post. It seems that, out of the nine members of the Board of Examiners, five were already members of the Court of Examiners, and these still belong to that Court. There seems to be no bye-laws prohibiting the Board from being made up entirely of members of the Court of Examiners.

Gunnislake, Devonshire.

Gunnislake, a village in the parish of Calstock, Tavistock Union, is at present suffering from a formidable attack of enteric fever. There are only 3000 persons in the village, and of these some 50 have been attacked. The disease is attributed to pollution of the water supply by fæcal matter washed into the reservoir by late rains. The sanitary condition of this village is described as being very bad indeed.

The Management of Irish Lunatic Asylums.

The inspectors in their recently issued report pay a high compliment to the local management or control of Irish district asylams. Of the scrupulous care bestowed by the boards of district asylums on all matters pertaining to current expenditure, the best demonstration is afforded in the fact that on an outlay amounting in round numbers, within the last seven years, to £1,100,000, after an annual investigation, lasting, one with another, five days in each establishment, by the Government auditors, no errors or irregularities, it may be said, were attributable to fiscal management, nor losses to the rate-payers during the whole period. As the word rate-payers has just been used, it may not be out of place to observe (avoiding very minute fractions) that the general taxable property of Ireland, out of which public asylums have been supported, amounts to £15,000,000 a year. The average cost of each lunatic in them in 1874, as already mentioned, was £25 2s. per annum, or probably a pound above that of the current year. The total outlay was £184,750, deducting from which the Government grant in aid, about £108,000 remained chargeable to the country, being at the rate of 1 3-5*d* in the £ on the preceding valuation. Were these lunatics located in the category of paupers in workhouses they would have entailed a public expense of £80,000, so the actual difference of outlay as between them in one receptacle and the other might be set down at £30,000—not ½d. in the £ in regard to taxation.

Prof. Bouchardat's Rules for Glycosuric Patients.

If the urine voided in twenty-four hours exceeds two and a-half pints, take as little fluids as possible, even such as soups, broths, &c.

Drink little at a time; rinsing the mouth with iced water will be found to give relief.

Thirst may be relieved by chewing, slowly, small pieces of dried cocoa, or better, olives, or coffee beans.

Two meals a day (one at 10, and one at 6) are better than three.

Avoid repose and sleep after meals, for which a walk after meals is useful.

Don't go to bed until four or five hours after the last meal.

Abstain from drinking coffee and smoking.

A Nile Sanatarium.

Dr. George Bird writes :—

"Having just returned from a steam voyage to the first cataract of the Nile, I think certain information I there gathered may prove welcome to many invalids whose means, or some other circumstances, may forbid the usual and hitherto sole mode of sojourning for the winter in Upper Egypt or Nubia.

"Until recently doctors were content to send a certain class of patients, chiefly *poitrinaires*, to winter at Cairo ; but for some years past, owing probably to the ever-widening area of irrigation, the multiplication of trees, and the greatly augmented surface of soil brought under cultivation, the climate of the charming city, though still better far than any to be found in Europe, has become notably moister, less equable, and consequently less suited to persons suffering from lung disease. Last winter, for instance, invalids were exposed to several sudden shifts from hot to cold weather, and on Christmas Day were longing for English fires.

Hence, in increasing numbers, patients are now advised to winter either in Upper Egypt or in Nubia, where, from November to the end of February, they may certainly insure a climate perhaps the finest in the world. But, obviously, to winter thus is possible only in the case of the very well-to-do, who can afford to make the journey luxuriously in a dahabeah. Now, as the hire of this floating pleasure-house and its attendant expenses go on every year augmenting at a ratio which before long must scare away from this delightful mode of travelling all but those armed with purses commensurate with the length of the Nile, it will, I think, to many, prove welcome news that Messrs. Cook and Son, to whom the Khedive has intrusted the complete control of the Nile steamers, will, early in January, 1876, establish a well-appointed sanatarium just above the first cataract. The situation chosen, on the right bank of the river, opposite the island of Philæ, just on the edge of the desert, close to a picturesque grove of well-grown palm trees, is perhaps the most beautiful to be found anywhere on the Nile.

"The first cataract is distant now but fifteen days' post from England. So ill-organised until lately, the post may now be relied on. There is a telegraph station on the island of Philæ. A steamer runs fortnightly from Cairo to the second cataract, and an invalid may start thence for the sanatarium in the middle of November. Medical aid *is by-and-by* to be forthcoming. The Messrs. Cook intend *to organise* a weekly service, and these enterprising gentlemen even talk of launching on the Nile commodious, luxurious, stately boats similar to those which ply on the American rivers."

The American Medical Centennial Celebration at Philadelphia.

A circular has been issued in view of the approaching celebration, which says that the medical societies of Philadelphia have taken the initiatory steps for the formation of an International Medical Congress, by the appointment of delegates from their respective bodies, who were empowered to organise and perfect a scheme for the above purpose, and who have organised "The Centennial Medical Commission," with the following officers :—

President.—Samuel D. Gross, M.D., LL.D., D.C.L., Oxon.

Vice-Presidents.—W. S. W. Ruschenberger, M.D., U.S.N. ; Alfred Stille, M.D.

Recording Secretary.—William B. Atkinson, M.D.

American Corresponding Secretaries.—Daniel G. Brinton, M.D. ; William Goodell, M.D.

Foreign Corresponding Secretaries.—Richard J. Dunglison, M.D. ; R. M. Bertolet, M.D.

Treasurer.—Caspar Wister, M.D.

Arrangements have been made for the holding of the Congress in the City of Philadelphia, to begin on the 4th and to terminate on the 9th of September, 1876.

The morning sessions of the Congress shall be devoted to general business and the reading of discourses ; the afternoons to the meetings of the Sections, of which there shall be nine, viz. :—

1. Medicine, including pathology, pathological anatomy, and therapeutics.
2. Biology, including anatomy, histology, physiology, and microscopy.
3. Surgery.
4. Dermatology and syphilology.
5. Obstetrics and diseases of women and children.

7. Sanitary science, including hygiene and medical statistics.
8. Ophthalmology and otology.
9. Mental diseases.

The language of the Congress shall be the English, but not to the exclusion of any other language in which members may be able to express themselves more fluently.

Gentlemen intending to make communications upon scientific subjects are requested to notify the Commission at the earliest practicable date, in order that places may be assigned them on the programme.

In order to impart to the Congress a thoroughly international character, invitations to send delegates will be extended to all the prominent medical societies in Europe, Mexico, the British Dominions, Central and South America, the Sandwich Islands, the East and West Indies, Australia, China, and Japan. Invitations will also be tendered to medical gentlemen of high scientific position ; and distinguished visitors may be admitted to membership by a vote of the Congress.

Among the advantages arising from such a convocation as this, not the least important will be the opportunity afforded its members for the interchange of friendly greetings, the formation of new acquaintances, and the renewal and cementing of old friendships.

The Centennial Medical Commission tender, in advance, to their brethren in all parts of the world, a cordial welcome, and a generous hospitality during their sojourn in the "Centennial City."

There is every reason to believe that there will be ample hotel accommodation for all strangers visiting Philadelphia in 1876. Further information may be obtained by addressing the Foreign Corresponding Secretaries—Richard J. Dunglison, 814 N. 16th Street, Philadelphia, R. M. Bertolet, 113 S. Broad Street, Philadelphia.

Lunacy in Yorkshire.

Lunacy seems to be alarmingly on the increase in Yorkshire. In the report of the visitors of the South Yorkshire Lunatic Asylum at Wadsley, presented on Thursday last, it is stated that although the asylum had only been opened about four years it already contained 605 patients, and if lunacy increased at the same rate this year as prevailed during last year the whole of the 862 beds would be occupied. The death rate last year was 15.23 per cent. on the daily average number resident, and the number of recoveries had been 43.96 per cent. Sites for building to increase the accommodation of the asylum had been approved by the Commissioners in Lunacy. These buildings would afford accommodation for 303 men and 307 women.

Adulteration Items.

It has always appeared to us strange that our medical officers of health, in their capacity as guardians of the public diet, should have paid so little attention to the stuff sold to the public. To put it very mildly, the inhabitants of the United Kingdom somehow manage to consume a

not inconsiderable quantity of spirits, whisky being the most popular. No one better than medical officers of health can possibly know how many thousands are slowly poisoned or maddened by the deleterious compounds out of which retailers make such large profits, and yet, with a few isolated exceptions, they have been allowed to carry on their nefarious traffic, untouched by that law which has been made for their punishment. Perhaps the example of Professor Anderson, the analyst for Paddington, may induce others to bestir themselves. In his quarterly report to the vestry there are some startling facts respecting the composition of "whisky" and "butter." During the past thirteen weeks he has analysed twenty samples, sixteen being of butter, three of whisky, and one of tea. Referring to the whisky, Prof. Anderson says, "it was found not to be the article at all, but a raw fiery spirit;" and intimates that proceedings have been instituted in the "whisky" cases. Some of the samples of butter he considered to be as flagrant cases of concoction as he had yet met with. Besides being made up of fatty ingredients, not butter, salt and water were found to be largely incorporated with it. The analyst goes on to state that within the last three months he has examined thirty specimens of butter, inclusive of sixteen taken from Paddington, and of these nineteen contained exactly 4 per cent. of water and common salt varying from $1\frac{1}{2}$ to $3\frac{3}{4}$ per cent. In "dairy" butter the proportion of salt and water was subject to some variation, but it was not found to exceed 2 per cent. He adds that the result of his examination has been to convince him that there exists a systematic manufacture of adulterated butter, and to make him believe that both butter and lard are being extensively mixed by a sort of pug mill in which they are blended together with salt and water and flavouring matter. The vestry have, upon his report, ordered prosecutions.

In Dr. Stevenson's report for the St. Pancras district last week the following items appear: Of six samples of porter three were salted with common salt, to the extent of 54 grains per gallon, which made it yeasty and unwholesome. Twenty-eight samples of sherry were fortified by spirits, and contained 41 grains per bottle of sulphate of potash, derived from sulphate used in stopping fermentation, or from plaster of Paris, used in the process of plastering white wines, brandy, &c. Both gin and brandy were found largely diluted by water.

In the course of proceedings connected with a case in the London Bankruptcy Court on Saturday, it was stated that the stringency with which the provisions of the Adulteration Act of last session had been carried into effect had caused a large number of failures in the milk trade. So much the better for the public.

Betts v. the "Medical Press and Circular."

In the Medical Press and Circular of November 10th, 1875, we quoted from our spirited contemporary the *Students' Journal and Hospital Gazette* the statement of a correspondent in reference to a dispensary kept by a Mr. Jas. Oliphant Betts, at 53 Exmouth Street, Clerkenwell, at which he purported to give advice and medicine to his patients for *fourpence*, and we expressed ourselves in terms of disapproval of such line of practice, declaring our belief that, though it was quite possible for him to give his advice for such a sum, it was not *commercially* possible to supply medicine of the best quality, of the necessary efficiency, and in sufficient quantity to a promiscuous assemblage of patients at 4d. per head if a profit were supposed to be made. Shortly after the publication of this extract, with our observations thereon, we received a legal communication demanding the name of the author.

On reperusal of the statement which we had made, and on consideration of what we owe to our own independence of speech, and especially to the feeling of the profession, we felt ourselves obliged to refuse this request, and to accept the task of establishing—if necessary—at law the truth of our statement and the *bona fides* of our intention, which we have every confidence that we shall do if Mr. Betts sees his way to a contest with us. We have received the usual legal documents, intimating Mr. Betts's determination to sue for £1,000 damages, and, acting under advice, we have taken the necessary steps for defence, and we shall feel it a satisfaction to be permitted to defend in open court the profession and the public against the sort of practice which we have condemned in Mr. Betts. As to the personal bearings of the matter, we may say that we never even heard the name of this gentleman until it had been brought under notice in the *Students' Journal*. We performed a public duty in a manner which we are prepared to justify, and we apply our censure equally to all practitioners engaged in similar practice—if such there be, feeling confident that on this as on several previous occasions when our public duties have forced us to speak out, we shall be backed by the support of the whole profession.

Pharmacy in Ireland.

The monthly meeting of the Irish Pharmaceutical Council was held in the College of Physicians, Kildare Street, on Wednesday last, Sir D. Corrigan, President, in the chair. The following members were present:—Mr. Wm. Allen, Dr. Collins, Dr. Frazer, Mr. J. Goodwin, Mr. W. Hayes, Mr. E. M. Hodgson, Mr. J. T. Holmes, Dr. Leet, Dr. Macnamara, Mr. R. W. Pring (Belfast), Dr. Reynolds, Dr. Ryan, Dr. A. Smith, and Professor Tichborne. A communication was read from the Privy Council in reference to the bye-laws of the society. Several alterations, principally of a verbal nature, and in reference to the working of the society, were suggested by the law officers of the Crown, and adopted by the society.

We understand that one emendation of a peculiarly significant character was suggested by the Privy Council. The decision of the Pharmaceutical Council not to create a second grade of dispensers in Ireland, but to confine the qualifying function of the society to the one licence of Pharmaceutical Chemist, was referred to, and an anticipation expressed that the Council might yet change its mind on this point. It was therefore suggested that the Council should interpolate some words which would leave it open to them to adopt the second grade if they pleased, and it was decided to introduce the words "for the present" into the clause referring to the matter.

We hope that this hint of the Privy Council may be interpreted as expressing an opinion in high quarters that there ought to be two grades of dispensers in Ireland.

The Tuckabo.

At a meeting of a pharmaceutical society of Philadel-

phia, Dr. Miller presented a curious fungous growth obtained from the South, where it is occasionally found as a parasite on the roots of larch trees; in the far West it is used as an article of food by the Indians, and is known as tuckabo, or Indian head. Its botanical name is *Lycoperdon solidum*. It contains about 82 per cent. of starchy, and 4 per cent. of nitrogenous matter, so that it is highly nutritious. Occasionally the fungus attains large dimensions, equalling a man's trunk in size, or resembling a human head in shape, whence the name of Indian head.

Dangers of Apomorphia.

Dr. Prevost, of Geneva, reports a case in which he injected subcutaneously 3 or 4 milligrammes of apomorphia in a woman suffering from sore-throat, with gastric disturbance. A state of collapse tending to syncope was produced, which continued for fifteen or twenty minutes, during which the pulse could scarcely be felt, and the pupils were dilated. In this instance the customary vomiting was established at the end of five minutes, and was repeated several times. The patient fell into a deep sleep, which lasted for about half an hour after the period of collapse. Several equally threatening cases have been reported by others.

The Compounding of Prescriptions.

Mr. Allen, analyst for the borough of Sheffield, has, says the *Standard*, issued a report of a somewhat startling character. In it he states that considerable anxiety exists as to the care and accuracy of druggists in making up physicians' prescriptions. In order to test the accuracy of these suspicions the inspectors of the Health Department presented to certain druggists various prescriptions written by qualified men. The prescriptions were so arranged that each should include a full dose of some expensive remedy, capable of ready and accurate estimation in a mixture. A series of three samples, in which 120 grains of iodide of potassium were prescribed, were found on analysis to contain 122, 120 and 76 grains respectively. The last was, therefore, made up with hardly two-thirds of the active ingredient ordered—a grave departure from the prescribed amount. Of three samples which should have contained 16 grains of sulphate of quinine, one contained only 9½ grains, or less than two-thirds of the prescribed amount. Another sample, which should have contained 40 grains of sulphate of quinine, had but 30 grains. Of twelve samples of glycerine, only five were pure and of the standard strength. Two other samples were somewhat below the official strength, containing 6 and 8·5 per cent. of water respectively, but were otherwise pure. Two others were adulterated with 11 and 12 per cent. of water. Two were of full strength, but contained lime and some non-volatile organic impurity. Another sample contained a small quantity of cane sugar. Three samples of citric acid were found to contain a minute trace of lead. In other respects they were perfectly pure. With reference to eleven samples of pepper, Mr. Allen states that nine were genuine, one was adulterated to a moderate extent with pea-flour, and the other to a moderate extent with rice. The Health Committe have decided not to take any proceedings against the druggists whose medicines were defective.

Poisonous Work in the Dockyards.

The medical officers of the royal dockyards have laid before the Admiralty a return setting forth the deadly effects produced upon the workmen by the plan of coating the inside of ironclads with red lead. A Plymouth contemporary states that the condition of the men is most pitiable. Lead colic is very prevalent, and the work is so injurious that every hour the men are obliged to go on deck to breathe fresh air and to wash their mouths out and drink a preparation of sulphuric acid. In spite of these measures their teeth drop out, the hair falls off, and graver results will inevitably follow. Respirators have been tried, but it is next to impossible to breathe in the close atmosphere with them, and the evil continues.

Camphor Poisoning.

The *Pharmaceutical Journal* publishes a rare and interesting case of camphor poisoning, the leading features of which are as follows—:

While some camphor was being weighed out, a lad of thirteen picked up two small pieces and took them away with him for the purpose of floating and burning them. Soon afterwards he began nibbling the camphor, and, as it afterwards appeared, liking the taste of it, continued to do so until he had eaten the two pieces. This was about four o'clock in the afternoon. Four hours afterwards the child was with his brother in the dispensary looking on, and was observed to do something which elicited the remark, "Are you dreaming?" No reply was given by the child, and it was noticed that something was wrong with him: his eyes were fixed in a stare, and he stood motionless and unconscious. His brother took him up to carry him into an adjoining room where his father was, when he immediately became convulsed and perfectly rigid, with his head and legs bent back, so that he could only be placed on his side upon the floor. The convulsions increased until the flesh from the head to the shoulders became purple, and the pulse decreased rapidly until it could not be felt. The body then lost its rigidity and was apparently lifeless; but in about ten seconds the pulse could again be felt, the convulsions returned, and the child foamed at the mouth. Applications of cold water brought him round in about four minutes; violent vomiting then ensued; the child was for a time hysterical, but within an hour from the first attack he was so far recovered that he could be put to bed. The child afterwards described the pieces of camphor which he ate as being each half the size of his thumb, and the assistant who noticed him take one piece thought it must have been about sixty grains in weight. The effects produced in this case were more severe than in any of those previously reported, and there was the further difference that unconsciousness preceded the convulsions, while in the other cases it followed them.

Dr. Banks, ex-President of the King and Queen's College of Physicians in Ireland, has been placed by his Excellency the Lord Lieutenant on the Senate of the Queen's University in the room of Mr. Adams.

Dr. Head has been appointed Consulting Physician, and Dr. George F. Duffey, Physician, to the National Institution and Molyneux Asylum for the Blind of Ireland.

Of the 7,585 lunatics now in Irish district asylums, there are 18 medical men, 7 lawyers, and 113 students and teachers. Of the 672 who are confined in private asylums,

9 were medical men, 13 were lawyers, 19 clergymen, 28 army officers, and 32 students.

THE election of a surgeon to Swift's Hospital for Lunatics, Dublin, in the room of the late Mr. John Hamilton, was a second time attempted on Monday week last. On the first occasion, a month since, the vote of the Governors resulted in a tie of 3 to 3. On this occasion the votes were again equal, the poll being 4 to 4. The candidates are Mr. Colles and Mr. Thornley Stoker.

THE Medical Society of the College of Physicians of Ireland will meet this evening (Wednesday) at 8 o'clock, at the College Hall, Dublin, when the following communications are set down for reading:—Dr. J. W. Moore, on "A Case of Pyæmia, with Sudden Destruction of the Eye-ball;" Dr. MacSwiney, on "A Case of Cirrhosis of the Liver;" Dr. W. G. Smith, on "A Case of Hydrocephalus;" Dr. Finny, on "A Case of Dermatitis Exfoliativa."

THE new hospital at Grantham, which has been erected on a commanding site at the entrance to the town, was opened by the Countess Brownlow last week, in the presence of the Lord Lieutenant, the Bishop of the diocese, and a distinguished assemblage. At the luncheon the Earl Brownlow presided. After the usual toasts Sir Hugh Cholmeley, M.P., proposed "Success to the Grantham Hospital," and took occasion to remark upon the architectural picturesqueness of the exterior of the buildings, and the comfort and convenience of the interior arrangements. The works have been carried on under the direction of and from designs prepared by Mr. R. A. Came.

A LEGAL case of considerable interest—which pressure on our space prevented us noticing sooner—was tried in Dublin at the last after-sitting, and resulted in a verdict which will be of value to the profession in deciding their rights as regards fees in private cases. Mr. Croly, Surgeon to the City of Dublin Hospital, had been, for the best part of a year, in continuous and harassing attendance on a gentleman of property in Dublin, the nature of the disease being specially unpleasant. In the course of the attendance he had paid 470 visits, most of them on special summons, or at the special request of the patient, and nearly 80 of them in the night. Having restored the patient to health, Mr. Croly was asked to name his fee, which he stated at £300, but the patient objected to give more than £200, and it became necessary to enforce payment of the balance. The issue for the jury was whether the sum demanded by Mr. Croly was reasonable, bearing in mind his position as a surgeon, the nature of the disease, and the times at which the attendance was required to be given. On this point Dr. Banks, the President of the College of Surgeons, and other leading members of the profession testified that they considered the fees demanded quite just and proper, and a moderate remuneration for a surgeon of Mr. Croly's eminence under the circumstances, and the jury unhesitatingly gave a verdict for the full amount.

There is an ancient tradition of the profession, that to sue for recovery of fees is scarcely *de rigueur*—an idea which Mr. Croly deserves credit for having had the courage to dissipate. We should object to the practice of litigation, but there are occasions, like the present, in which the surgeon who asserts his rights does a simple duty to his brethren. If Mr. Croly had accepted an inadequate fee, he would not only have done himself an injustice, but he would have made public the impression either that his services were worth no more or that medical men are obliged to take what they get and be thankful.

Correspondence.

HANGING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems strange to me that the Surgical Society of Ireland should have considered the best mode of hanging, and not also the best mode of putting criminals to death.

It must add to the horror of death to know that it is to come in a most violent shape. The person sentenced to death will know now that he is to get his neck broken, and he is expected to believe that that mode is an improvement on hanging. I would venture to bet that six out of seven criminals, if they had their choice, would prefer hanging or strangulation to neck-breaking.

But why should either of these modes be used? Why not use a narcotic poison and permit the criminal to die quiety in bed? I would certainly vote for this mode of capital punishment: capital it still would be, as the head is the first to die in it.

If this mode were adopted capital convictions would be more frequent, I believe; but that as it may be, the mode of death would be much easier, less barbarous, less horrifying, less appalling, and more welcome to the culprit.

The Greeks would have used morphine had they known it. Hemlock, the best narcotic they knew, they did use. We might use several narcotics; and if surgeons here and elsewhere were permitted to guide their application, valuable information might be thus obtained to medical science.

Should a criminal refuse the morphine or other poison, we could use carbonic acid gas, æther, or chloroform. These, too, could be used in conjunction with the narcotics, if necessary. Montgomery, it is said, asked the hangman if hanging was a painful death and got a flippant answer. Death by a narcotic is of course painless; by it, too, the pomp and circumstances of a public or a semi-public execution, which has a bad effect on the mind of the criminal, would be prevented, and a quiet and resigned state would be produced by knowing that the long sleep in the narrow house would be only preceded by a painless and unbroken sleep in a private bed in jail. Surely this kind of death better suits the charitable tone of the present time than death by violent fracture of the spine.

It might be worth discussing whether the poison should be given with or without the consent or knowledge of the criminal. In my opinion the poison-cup would be quaffed without hesitation by six out of seven criminals—would be taken certainly without any such dread as is created by the gallows drop and neck-break fall.

MEDICUS.

Medical News.

Vital Statistics.—From the Registrar-General's returns we learn that during last week 5,943 births and 4,052 deaths were registered in London and twenty other large towns of the United Kingdom. The mortality from all causes was at the average rate of 27 deaths annually in every 1,000 persons living. The annual death-rate was 27 per 1,000 in London, 22 per 1 000 in Edinburgh, 26 in Glasgow, and 33 in Dublin. The annual rates of mortality per 1,000 during the same period in the other large towns were—Portsmouth 23, Norwich 23, Leicester 25, Wolverhampton 23, Sunderland 20, Bradford

24, Birmingham 26, Bristol 30, Sheffield 26, Leeds 22, Nottingham 23, Liverpool 30, Newcastle-on-Tyne 27, Manchester 33, Salford 33, Oldham 39, and Hull 36. The annual death-rate from the seven principal zymotic diseases averaged 4·2 per 1000 in these towns, and ranged from 1·0 and 1·1 in Sunderland and Newcastle-on-Tyne, to 8·8 in Salford. Scarlet fever was again fatally prevalent in Salford, Bristol, Leicester, and Leeds. Six deaths were referred to fever in Sheffield, raising the fatal cases in the past thirteen weeks to 108; there is no hospital for the isolation and treatment of infectious diseases in Sheffield. In London, the 1,782 deaths included 75 from scarlet fever, 20 from different forms of fever, 16 from diarrhœa, and not one from small-pox; thus in the zymotic class 272 deaths were referred, against 311 and 253 in the two preceding weeks, or 5 above the corrected average. The 20 deaths referred to fever were no less than 27 below the corrected average number in the corresponding week of the last ten years; one was certified as typhus, 14 as enteric or typhoid, and 5 as simple continued fever.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Royal College of Physicians of London.—The notices of lectures at this College was, by a printer's error, published in our last under the head of Royal College of *Surgeons*.

Dr. Patrick Black, Physician to St. Bartholomew's Hospital, has just published a pamphlet entitled, "Why do we Breathe?" We are certainly surprised that Dr. Black as a physiologist should consider it necessary to ask such a question on the outside of his book!

Clinical Society of London.—On Friday next, at 8½ p.m., the Annual Meeting will be held. Afterwards the following papers will be read: Dr. T. S. Dowse, "On a Case of Thrombosis of Cavernous Sinus; Sudden Loss of Vision; Hæmorrhage into Anterior Lobe." Mr. Venning, "On a Case of Congenital Tumour." Mr. C. Heath, "On a Case of Gunshot Wound of the Arm, dividing the Brachial Artery and Median Nerve."

To the Editor of the Medical Press and Circular.

Sir,—I would esteem it as a great favour if you would have the kindness to answer the following questions in the next edition of your valuable paper. Preparatory to my stating the questions I wish to have answered, I beg to state that I intended (as I had a medical friend residing in London) to take out my lectures there, and acting on that intention, I paid to one of the medical schools in London the amount of money required for the first two years of my course. I find since then that I am unavoidably prevented from going over to London this year, as I am obliged by family circumstances to reside in Dublin for the next six months at least, during which time I could easily attend the lectures for the winter session in the latter city. The questions I wish to ask are these—First, Will the College of Surgeons in England recognise a certificate from any of the Dublin medical schools as having attended the first year's course of lectures so as to enable me (if I were competent at the time) to go in for my examination, after having attended three years' lectures in London? and secondly, will the school of medicine in London to which I have paid my money for the first and second years' lectures allow me to attend the second and third years for the amount already paid for the first and second years' lectures if I pay any additional expense that may be incurred, as I believe the lectures for the third year are more expensive than those of the first, and explain to them the circumstances under which I was placed, and show them the certificate of having attended the first year's lectures in Dublin from one of the Dublin schools of medicine.

I remain, Sir,

Yours truly,

Dec. 31, 1875. Medicus.

[Your letter arrived too late for reply in our last. The London College will accept all certificates granted by recognised Dublin schools. We believe that any school in London will allow you to transfer your attendance to second and third years as you wish.—Ed. M. P. & C.]

Dr. Abbath, Sunderland.—Our publisher, or any bookseller will supply you with reading cases for this journal; they are generally announced in each number.

Dr. Shaw, Rotherham.—Received, and will have attention.

Mr. Cross.—The work you mention was published in 1856; it is now out of print, and cannot, we believe, be purchased at any price. The name of the author was not known, although its origin was undoubtedly from one of the departments of the army.

A Constant Reader will find the case referred to in another column.

Quack v. Quack.—A case was tried last week at the Stafford Sessions —Clarke v. Kelly, M.B., the plaintiff being the proprietor of the notorious "Clarke's Blood Mixture," and the defendant a man who described himself as a medical botanist, which the degree of M.B. after his name was intended modestly to express. The said defendant had sold two bottles of his precious medicine to a woman for 2s8., she imagining she was purchasing Clarke's Mixture. Clarke prosecuted in order to protect his patent rights, for which he stated he paid Government £7,000 a year stamp duty. After long arguments on both sides by counsel, wherein the whole affair was stigmatised as "quack v. quack," the jury returned a verdict of not guilty.

F.R.C.S.—According to the construction put upon it, the object and intention having most weight in the result.

The Howard Medal.—We are requested to state that Mr. James Heywood, F.R.S., President of the Statistical Society, has given the sum of £20 to be presented with the "Howard Medal" in November next. The essays, as already announced, are to be sent in on or before the 30th June, 1876. The title of the essay is, "On the Mortality of Hospitals (General and Special) in the United Kingdom in Times Past and Present."

Communications, Enclosures, &c., have been received from—Mr. Gray, London. Dr. Little, London. Dr. Byrd, Quincy, America. Dr. J. C. Mackenzie, Cincinnati. Surg.-Major Porter, Woolston. Dr. C. Bell Taylor, Nottingham. Dr. Byford, Philadelphia. Mr. Tatham, Brighton. Mr. Margetson, Dewsbury. Prof. Amos, University College. Dr. Davies, Abergele. Mr. Gaskoin, Westbourne Park. Dr. Chapman, Paris. Dr. Shaw, Flanderwell. Dr. Lafarelle, Coleshill. Major-General Creagh, London. Mr. R. Hanslip Sers Epperstone. Dr. E. S. White, Fowey, Cornwall. Mr. Norton, Whitchurch. Dr. Williams, Fulham. Dr. Seward, Templegune. Dr. Storey, Borrisokane. Dr. O'Doherty, Carndonagh. Dr. Davison, Dromara. Dr. Seymour, Baltinglass. Dr. Smith, Lancashire. Dr. Ivers, Ballyshannon. Dr. Sterling, Thomastown. Dr. Carey, Borris. Dr. Ryan, Dublin. Dr. Brodie, Galway. Dr. Nunan, Kinsale. Dr. Browne, Dundalk. Dr. Trotter, Meath. Dr. Robinson, Dublin. Dr. Cromie, Clough. Dr. Richardson, Dublin. Dr. Evans, Dublin. Dr. Sharkey, Ballinasloe. Dr. Widdup, Dungloe. Dr. Kidd, Rathvilly. Dr. Ryan, Tipperary. Dr. Gilmore, Malin. Dr. Percival, Stradbally. Dr. White, Tubbercurry. Dr. Wolseley, Dunfanaghy. Dr. Harold, Castleisland. Dr. Shiel, Killyleigh. Dr. Reardon, Kilcorrery. Dr. West, Rathmelton. Dr. W. J. Little, London. Dr. Pinder, Harpurhey. Dr. Habershon, London. Dr. Abrath, Sunderland. Dr. Collenette, Guernsey. Mr. J. Birchenall, Macclesfield. Mr. Batstone, St. Leonards'. Mr. Geo. Gray, Speenhamland. Mr. Betts, Clerkenwell. Mr. Tamplin, London. Dr. Fixott, St. Heliers, Jersey. Mr. Redman, Lincoln. Mr. Walter Rivington, London. The Trustees of the John Hopkins Hospital, Baltimore. Mr. Benthin, London. Dr. Carey, Taunton, &c., &c.

VACANCIES.

Carlow Union. Bagenalstown Dispensary District. Medical Officer. Salary, £100, exclusive of £20 as Sanitary Officer. (See Advt.)

Birmingham. Assistant Workhouse Medical Officer. Salary, £100, with furnished apartments, &c. Endorsed applications to be sent to the Parish Offices, Paradise Street.

Liverpool Ear and Eye Infirmary. House Surgeon. Salary, £80, with board. Apply to the Hon. Treasurer, 8 Knowsley Buildings, Liverpool.

Derby Infirmary. Assistant House Surgeon. Board, lodging, and washing, but no salary. Address the Secretary.

Homerton Fever Hospital. Medical Officer. Salary, £120 per annum, with board, &c. Address the Medical Superintendent.

Brighton and Hove Dispensary. Resident House Surgeon. Salary, £120, with furnished apartments. Applications to the Chairman of Committee.

APPOINTMENTS.

Bullock, H., F.R.C.S.E., Medical Officer of Health for the Heston and Isleworth Urban Sanitary District.

Cooper, A., M.R.C.S., House-Surgeon to the Male Lock Hospital, Dean Street, Soho Square.

Cripps, W. H., F.R.C.S., Surgeon to the Great Northern Hospital.

Cunynghame, R. J. B., M.D., F.R.C.S.Ed., Conservator of the Museum of the Royal College of Surgeons, Edinburgh.

Duffey, G. F., M.D., F.K.Q.C.P.I., Physician to the National Institution and Molyneux Asylum for the Blind of Ireland.

Ewart, W., M.R.C.P.L., M.R.C.S.E., House-Physician to the Addenbrooke Hospital, Cambridge.

Gibbons, R. A., M.B., C.M., M.R.C.S.E., House-Surgeon to the East Suffolk and Ipswich Hospital.

Marriages.

Bowen—Melhuish.—On the 5th Jan., at St. Stephen's Church, South Dulwich, Essex Bowen, M.D., Birkenhead, to Edith, eldest daughter of William Melhuish, Dulwich Wood Park.

Hopgood—Knight.—On the 4th Jan., at St. Paul's Church, Cheltenham, Thomas Hopgood, Esq., M.R.C.S.E., to Elizabeth S. Knight, both of Chipping Norton.

Redmond—Power.—On the 4th Jan., per special licence, at the residence of the bride's father, John Joseph Redmond, L.R.C.S.I., L.K.Q.C.P.I., to Kate, youngest daughter of Thomas Power, Esq., St. Leger Place, Tramore.

Deaths.

Brown.—On the 4th Jan., at Kennington Park, Thomas Brown, M.D., aged 51.

Cannell.—On the 23rd. Dec., at Accrington, John Cannell, M.D., aged 34.

Corsellis.—On the 1st Jan., at Oxford, Charles Cæsar Corsellis, M.D., aged 75 years.

Edwards.—On the 1st Jan., at Sparkbrook, Birmingham, John Edwards, M.D., aged 48.

M'Keand.—On the 29th Dec., at Oxford Road, Manchester, Joseph M'Keand, M.R.C.S.E., aged 51.

Moorhouse.—On the 26th Dec., at West Broughton, Lancashire, Henry Moorhouse, L.R.C.S.I., aged 33.

Wilson.—On the 31st Dec., at Denton House, Elphinstone Road, Southsea, Hants (the residence of his brother, Thos. G. Wilson, Staff-Surgeon, R.N.), Robert Wilson, M.D., Surgeon-Major, Madras Army, aged 48.

Wright.—On the 3rd Jan., at Markfield, Leicestershire, Samuel Wright, M.R.C.S.E., aged 74.

"PRESERVATION OF SIGHT."

IT IS NECESSARY to UNDERSTAND that PRESERVATION of SIGHT does not depend in all cases upon wearing Spectacles, nor does it depend upon not wearing them. If Spectacles are worn when there is no necessity, or if not used when Nature is calling for assistance, evil results will accrue. It would be therefore well for persons about buying a pair of Spectacles to consult an optician having an intimate knowledge of the anatomical structure of the eye, an extensive acquaintance with the science of Optics, and a practical acquaintance with the manufacture of Lenses and Spectacle Frames.

"Natural Decay of Vision." Such usually occurs from thirty to fifty years of age, according to the habits of the individual; the eye loses its power of seeing near objects; reading by artificial light becomes more difficult, and in order to see more distinctly the light is often placed between the book and the eye; fatigue is felt, and reading after a short time must be discontinued.

"Short Sight."—Short sight is generally present at birth, but is not observed until a certain age has been attained, or until study calls attention to it.

HYPERMETROPIA, OR OVER SIGHT.

"Long sight." "Unequal refraction." "The eyes, after having been operated upon for cataract," "Strabismus," "Astigmatism," "Diminished or morbid vision caused by using improper glasses," all require the assistance of Lenses, but to adapt the proper one to each particular case too much caution cannot be observed,

THE OPTOMETER.

Mr. SEACOME MASON, having an Optometer and Ophthalmoscope Room attached to his establishment, is enabled in all the above cases of Defective Vision to adapt Lenses, which to extreme old age will be of ease and comfort, conferring a boon upon the wearer, often wished for but seldom experienced.

It is unnecessary to call attention to S. M.'s Spectacles, having enjoyed a reputation of many years' standing, his being the oldest Optician's Establishment extant in Ireland.

S. M.'s Spectacles and Eye Glasses have been used by the Nobility, Gentry, Clergy, and members of the Medical Profession in Ireland, including—

His Grace the Duke of Leinster.	The Right Hon. the Earl of Erne.
The Right Hon. the Earl of Leitrim.	The Right Hon. the Earl of Bantry.
The Right Hon. Viscount Gough.	Lord Sandhurst, Commander of the Forces
The Lord Fitzgerald.	The Right Honourable Lord O'Hagan.
Sir Frederick Shaw, Bart.	Sir A. Guinness, Bart.
Sir Gilbert King, Bart.	Sir Percy Nugent.
The Archdeacon of Cashel.	
The Dean of St. Patrick.	

Also by the late Sir John Gray, M.P., J.P.,
And both used and recommended for over 50 years by the late
DOCTOR JACOB
SEACOME MASON, STATE OPTICIAN,

For Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of
WILLIAM STARKEY, M.D.,
Licentiate Apothecary.

EVANS' EXTRACT OF MALT.

This PURE Preparation of Malt, combined with the aromatic bitters, possesses in a most remarkable degree the elements admirably adapted for yielding

NUTRITION TO PERSONS OF
CONSTITUTIONAL DEBILITY,
OR THOSE SUFFERING FROM LOSS OF APPETITE,
OR FROM ENFEEBLED DIGESTION.

Dr. Apjohn in his analysis states—"Of its constituents he most remarkable are those which *include Nitrogen*, the amount of which is unusually large—reaching as it does nearly 5 per cent. The *Proteinic* compounds in an ounce of it weigh 22·32 grains, and the analogous compounds in an ounce of beef-steak 98·43 grains. Hence, weight for weight, the *alimentary value* of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, *nutritious in a high egree, and being no doubt esy of assimilation, it must constitute an useful supplementary food in cases of debility and weak digestion.*"

Mr. Tichborne writes—"It is particularly rich in the *Phosphates*, the value of which, from a *nutritive* or *medicinal* point of view, is becoming more palpable every day. Other preparations of this class which I have examined, on evaporation, yielded only 36 grains of Extractive to the fluid ounce, whilst yours contain 101·5 grains.

Dr. Arthur Hill Hassall (author of "Food, Water, and Air, in relation to the Public Health;" "Food and its Adulterations," &c.), London, writes—"Evans' Extract combines soothing, sedative, stimulant, tonic, and nutritive properties, which render it a most valuable remedy in cases of debility, and in many affections of the respiratory organs.

Professor Attfield, Ph D., F.C.S., &c. (author of a "Manual of General and Pharmaceutical Chemistry." and Professor of Chemistry to the Pharmaceutical Society of Great Britain, Bloomsbury Square), London, writes—"It is a powerful restorative and gentle stimulant, and is highly nutritious in its flesh-forming, bone-forming, and general tonic characters. Evans' Extract is incomparably more valuable than any preparation of Malt hitherto offered to the public."

UNPARALLELED SUCCESS OF
GOODALL'S WORLD-RENOWNED HOUSEHOLD SPECIALITIES
A single trial solicited from those who have not yet tried these splendid preparations.

GOODALL'S BAKING POWDER.
THE BEST IN THE WORLD.
The cheapest because the best, and indispensable to every household, and an inestimable boon to housewives. Makes delicious Puddings without eggs, Pastry without butter, and beautiful light Bread without yeast. Sold by Grocers, Oilmen, Chemists, &c., in 1d. Packets, 6d., 1s., 1s. 6d., and 2s. Tins.
Prepared by Goodall, Backhouse & Co., Leeds.

YORKSHIRE RELISH.
The Most Delicious Sauce in the World.
This cheap and excellent Sauce makes the plainest viands palatable, and the daintiest dishes more delicious. To Chops, Steaks, Fish, &c., it is incomparable. Sold by Grocers, Oilmen, Chemists, &c., in bottles, at 6d., 1s., and 2s. 6d. each.
Prepared by Goodall, Backhouse & Co., Leeds.

GOODALL'S QUININE WINE
The best, cheapest and most agreeable Tonic yet introduced. The best remedy known for Indigestion, Loss of Appetite, General Debility, &c., &c. Restores delicate invalids to health and vigour.
Sold by Chemists, Grocers, &c., at 1s., 1s. 1½d., 2s., and 2s. 3d. each bottle.

Prepared by **Goodall, Backhouse & Co., Leeds.**

DR. HASSALL'S FOOD
FOR INFANTS, CHILDREN AND INVALIDS.

DR. ARTHUR HILL HASSALL, M.D., recommends this as the best and most nourishing of all Infants' and Invalids' Foods which have hitherto been brought before the public; it contains every requisite for the full and healthy support and development of the body, and is, to a considerable extent, self-digestive. Recommended by the Medical Press and Faculty. Sold by Grocers, Druggists, Oilmen &c., in Tins, at 6d., 1s., 2s., 3s 6d, 6s., 15s., and 28s. each.

A TREATISE by Dr. ARTHUR HILL HASSALL, M.D., on the "ALIMENTATION of INFANTS, CHILDREN, and INVALIDS," can be had, Post Free, on application, from the Manufacturers.

GOODALL, BACKHOUSE & CO., LEEDS.

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

TO THE EDITOR.

SIR,—I believe that the following case will be read with interest, and will prove useful by showing the value of Government regulations. It is also interesting as bearing on the subject of professional etiquette.

Having been lately appointed medical officer of a dispensary district, in consequence of the section of the Royal Irish Constabulary regulations given below, I wrote to the County Inspector, informing him of my appointment, and stated that I was ready to take charge of the police stationed in my district. I did this believing that I had as much right to the office of medical attendant to the constabulary as I had to be Registrar of Births and Deaths. I was aware that my predecessor did not hold the appointment; but I was also aware that although everyone considered this a most unjust thing, and that he did the greater part of the work, yet that he was withheld from applying for the appointment by private reasons. In due time I was sent a copy of the regulations as to duty, &c., with a request that I would certify that I would agree to them. I did so, and thought the matter settled. But at the end of the month I was informed that "as no complaints had been made against the medical man in charge, no change would be made."

Let it be remembered that the said medical man is medical officer of the adjoining district, and lives seven miles from one station and six miles from the other. I then wrote to the Inspector-General, and reminding him of the printed regulations, requested his decision on the matter. In answer, I received the letter given below. I refrain from commenting on the transaction, nor do I give names, in order that each of your readers may give an unbiassed opinion. I will only add that I am perfectly unacquainted with the medical man in question, never having even seen him.

I am, Sir, yours obediently,
A.B., M.D., M.C.

Royal Irish Constabulary Regulations (page 194).

855. All medical attendants of the constabulary are, IF POSSIBLE, to be those holding dispensaries. In the event of a dispensary doctor not wishing to have medical charge of the constabulary, then the most eligible professional man must be procured, taking into consideration, amongst other things, that his residence should be as central as possible in the district of which he is to have the oversight. In the event of a dispensary doctor who has charge of the constabulary resigning his dispensary, he must also give up his constabulary charge; but should his successor in the dispensary decline to be medical officer to the constabulary, then there will be no objection to his (the former medical officer) retaining the appointment if he wishes it, and is in all respects satisfactory and eligible. The medical attendants are required to attend the wives and children of the men in their charge.

"Royal Irish Constabulary Office,
"Dublin Castle.

"SIR,—In reply to your letter of yesterday, I am directed by the Inspector-General to inform you that as Dr. —— has satisfactorily discharged the duties of medical attendant to the —— and —— stations for a number of years, he will not be deprived of his position; but should a vacancy arise, your claim shall receive the consideration warranted by the regulations.

"I am, Sir,
"—— ——.

"It is to be remarked that your predecessor in the dispensary had not charge of these stations."

WORKHOUSE SICK NURSING.

AT the present time, when contagious disease is so prevalent, the desire is generally expressed that the workhouse hospitals be made use of largely by those at least for whom in their homes isolation, treatment, and attendance cannot be fully secured. Workhouse hospitals are numerous enough, are well situated and constructed, and provided with the best medical attendance to be had in the locality. There is one thing only which strikes us as being defective in their arrangements, viz., the paucity of skilled and responsible nurses. This defect was made very clear in the course of an investigation at the Dromore West Workhouse on Friday, it being elicited that a man seriously ill, though not at the time supposed to be dying, was left in charge of an idiot boy—accounted for by the fact that there was not another able-bodied person in the ward to take charge of the sick. The Board of Guardians would seem not to have been aware of the nature of the arrangements made for nursing the sick in hospital, and learning it on Friday, some of the members very strongly condemned them. But the course pursued at Dromore West would appear to be the rule, not the exception, in workhouse establishments. The case must be worse in those workhouses where the fever hospital is a separate building. It is thus in Ballina. For the numerous sick, divided between the fever hospital and infirmary, in separate buildings, there is only one paid, skilled, and responsible nurse. We have made it our business to inquire as to the attendance given to the fever patients especially, knowing that the hospital nurse could not do more than superintend the two establishments in her charge, and learn that they are left at night in charge solely of pauper nurses, women, as a rule, of loose habits and character. We have even heard of instances in which medicine prescribed for the sick, and given out for them, has been found in the morning unadministered. And this is only what might be expected with the class of nurse provided for administering medicines and medical comforts. The recent scare in the workhouse, when the pauper nurses were discovered drinking the wine and whisky, and giving none of it to the patients, will not be forgotten. Those nurses don't drink the medicine as the whisky, but it appears they leave it unadministered. A large hospital like that in Ballina, divided into two branches, in separate houses, should have more than a superintending nurse.—*Ballina Herald.*

COROFIN DISPENSARY.

A MEETING of the committee of management of this union was held recently for the election of a medical officer for the Corofin dispensary district (embracing the entire union) in lieu of Dr. M'Namara, who had resigned.

Colonel Paterson rose and proposed the appointment of Dr. George M'Namara as successor to their old friend and worthy doctor (hear, hear.). He was quite sure he would follow in the footsteps of his father, and earn for himself the confidence and esteem of all, by his attention and kindness to the poor, and in relieving the wants of all that required it. It would be folly for him (Col. Paterson) to make any further remarks about either Dr. M'Namara or Dr. George. They knew them well already. Dr. George M'Namara was then elected unanimously to the office.

Dr. M'Namara briefly returned thanks on the part of his son. He returned them his warm gratitude for the very unanimous manner in which they had elected him to the office. As he (Dr. M'Namara) was not separating himself altogether from the board, he trusted he would continue to deserve their kind consideration as he had hitherto done. He again returned them his warm thanks.

IRISH MEDICAL ASSOCIATION.

THE objects of the Irish Medical Association are—

To unite the members of the medical profession in Ireland, and so form an influential and highly useful body competent to protect and promote the interests of the profession generally, but especially those of the Poor-law and dispensary medical officers of Ireland, in the various departments under which they hold office.

To watch carefully the proceedings of Parliament upon matters affecting the interests of the members of the Association, and to take action with regard to same, with the object of promulgating its views amongst the members of Parliament.

To inform the members of the Association by circulars, to be issued from time to time, as occasion may require, of all matters affecting their interests, and so afford them an opportunity of expressing their opinions, and offering any information or suggestions they think fit.

To obtain, when considered necessary, legal advice as to the interpretation of the law upon matters involving the interests of the profession, and as it may seem expedient, to institute legal proceedings for the purpose of obtaining judicial decisions upon such matters.

To arbitrate in disputes between individual members of the profession, when such arbitration may be requested.

RULES.

I. That each Poor-law and dispensary medical officer, or any duly qualified physician or surgeon, may become and continue to be a member of the Irish Medical Association, subject to the approval of its Council.

II. That the annual subscription of each member shall be, at least, ten shillings and sixpence, payable at the beginning of each year; but any person who wishes to become a member after the 31st of March of any year, shall, upon payment of his subscription, be entitled to all the privileges of membership, not only for the unexpired portion of that year, but also for the ensuing year.

III. That each year shall commence on the 1st day of June, and terminate on the 31st day of May following.

IV. That the administration of the Irish Medical Association shall vest in the Council, who shall consist of the following:—

One President—to represent all Ireland.

Four Vice-Presidents—to represent the four provinces.

Thirty-two members—who shall, at their first meeting, to be held at the Royal College of Surgeons in Dublin, at four o'clock, p.m., on the Friday next after the day of the annual general meeting, appoint the following officers:—

One Honorary Treasurer,

One Honorary Secretary,

One Honorary Secretary of Council,

who shall be *ex officio* members of Council.

V. That the Council shall meet at least once in each quarter, and also from time to time, as occasion demands, when summoned by the Honorary Secretary.

VI. That the Council, at their first meeting in each year, shall appoint from amongst their number a Chairman of Council, and also a Committee consisting of seven members, including the Honorary Treasurer, the Honorary Secretary, and the Honorary Secretary of Council.

VII. That the duties of the Committee shall be—

To transact the financial business of the Association.

To direct meetings of the Council to be convened when they see fit.

To watch carefully all matters affecting the interests of the members, and to report on same to the Council.

To draw up and issue, from time to time, such circulars to the members as may be approved of by the Council.

To receive and deal with all matters of business and correspondence, not demanding, in their opinion, the special attention of the Council.

To carry into effect the instructions of the Council; but they shall not enter into any engagement which will make the Council, or the Association, liable for any sum beyond the amount which would remain in the Honorary Treasurer's hands to the credit of the Association, after providing for all previously existing liabilities.

VIII. That the various departments of the work of the Association shall be, by the Committee, so divided amongst its members that each shall specially be the province of one of them, viz.:—

To take cognisance of all matters affecting the interests of the profession generally; to watch, carefully, all Parliamentary proceedings affecting the interests of the members of the Association; and to bring same under the notice of the Committee.

To take cognisance of all matters affecting, specially, the interests of Poor-law and dispensary medical officers, and public vaccinators, as such, and to bring same under the notice of the Committee.

To take cognisance of all matters affecting the interests of registrars of births, deaths, marriages, and vaccinations, and to bring same under the notice of the Committee.

To take cognisance of all matters affecting the interests of sanitary officers, and consulting sanitary officers, under the Public Health Act, and bring same under the notice of the Committee.

IX. That an annual general meeting of the members shall be held an the first Monday of June in each year, at such time and place as may be appointed by the Council.

X. That the order of business at the general meetings shall be—

1. The minutes of last annual general meeting, and of all special general meetings (if any) since held, shall be read and confirmed.

2. The meeting shall appoint three scrutineers of the ballot, who shall decide, by lot, between candidates having an equal number of votes.

3. A ballot shall be opened, and shall remain open until the other business to be brought before the meeting shall have been disposed of, for the election of one President, four Vice-Presidents, and thirty-two members of Council.

4. The report of Council for the preceding year shall be read, setting forth the steps taken by them towards carrying out the objects of the Association.

5. The Council shall then submit an account of the whole income and expenditure of the Association, for the year ended the 31st day of May then last past, showing all arrears of income due, and any current liabilities unpaid, which account shall be signed by the Honorary

Treasurer, and the accuracy of which shall be certified by the Auditors.

6. The resolutions recommended by the Council shall then be separately brought before the meeting and dealt with.

7. Any member of the Association may then propose any resoluton which he desires to bring under the notice of the meeting.

8. All resolutions must be proposed by one member, and seconded by another, before being put by the Chairman to the meeting.

9. The result of the ballot shall then be declared by the Chairman.

10. Two members of the Association—not being members of the Council—shall then be elected to audit the accounts during the ensuing year.

XI. That at the meetings of the Council five members shall form a quorum.

XII. That at the meetings of the Committee three members shall form a quorum.

XIII. That the Honorary Treasurer shall receive all subscriptions, and issue receipts for same, and shall (with the sanction of the Committee) discharge all the liabilities of the Association, and submit the accounts of the Association to the Committee, to be examined by them when so required, at least once in each year.

XIV. That the Honorary Secretary and the Honorary Secretary of Council shall discharge all secretarial functions required by the Council or the Committee.

XV. That the Council may, whenever it appears to them expedient, direct that a special general meeting of the members of the Association be convened by the Honorary Secretary, to be held at such time and place as they appoint, to consider any matters deemed by them to be of such importance as to require an expression of the opinion of the members at large.

XVI. That the Council shall have power to make any bye-laws they deem necessary for the regulation of their own business, and to fill up any vacancy which may occur amongst their body.

XVII. That the Committee shall have power to make any regulations they deem necessary for the transaction of their special business, subject to the approval of the Council.

XVIII. That notice of each general meeting shall be given to each member of the Association, by circular, at least one week previous to the day of meeting.

XIX. That an annual dinner of the members of the Association shall be held on the first Monday of June, in each year, at such time and place, and under such regulations as the Council may approve.

XX. That none of these rules shall be altered or repealed, nor shall any addition be made thereto, unless at an annual general meeting of the Association, and notice of any proposed change, signed by its proposer and seconder, shall be communicated to the Honorary Secretary at least two weeks before the day of such meeting.

N.B.—All communications relating to subscriptions and financial business should be addressed to the Honorary Treasurer; those concerning all other matters should be addressed to the Hon. Secretary of the Irish Medical Association, Royal College of Surgeons in Ireland, Dublin.

CARLOW UNION.

RESIGNATION OF DR. TRAVER.

A letter was read by the chairman from Dr. Traver, Medical Officer of the Bagenaistown District, to the Dispensary Committee, tendering his resignation in consequence of ill-health, Dr. Banks, after mature consideration, being of opinion that that the resumption of the duties of the dispensary would be attended with risk to his life. In thus closing a relationship of nearly twenty-five years' duration he begged to return thanks for the confidence always reposed in him, and for the kindly feeling always shown him by every member of the Committee.

Chairman.—I am sure it is with great regret we accept the resignation of Dr. Trayer, who has served us so well, and with such zeal and skill, for twenty-five years.

Mr. Newton said a special meeting of the Bagenalstown Dispensary Committee was held on Wednesday to consider Dr. Trayer's resignation, and he was requested by tqem to state to the Board that they considered £100 a year would be sufficient remuneaation for the Dispensary Medical Officer in future, and to request the sanction of the Board to reduce it to that amount.

Mr. Fitzmaurice thought if the Dispensary Committee were of that opinion the Board could not have any oqjection to fix the salary at what they considered necessary. If they thought it desirable to increase the salary bye-and-bye they could do so, but in the meantime he thought they should advertise for a medical officer of the district at a salary of £100 a year.

Mr. Newton then proposed that Dr. Trayer's resignation be accepted, and that an advertisement should be inserted in the usual newspapers for a medical officer for the district at a salary of £100 per annum.

This proposition was unanimously adopted.

Mr. Newton then gave notice of his intention to move on that day month that Dr. Trayer be awarded two-thirds of his salary as superannuation allowance.

RED TICKETS IN OUT-DOOR RELIEF CASES.

A letter was read from Dr. Carey, Medical Officer for Borris district, referring to an out-door relief case ruled on Relieving Officer's book, in which certificate was required from him (Dr. Carey) as to the man's fitness to be removed. Dr. Carey observed that he never refused to give a certificate as to the state of health of any patient under his charge. In this instance at the request of the man's wife he sent a recommendation to the Relieving Officer to give the relief, but received a second red ticket to visit the man to certify whether he was fit or unfit for removal. He wished to be informed whether or not in the case of a person applying for out-door relief, the Relieving Officer was empowered to issue a red ticket requiring the attendance of the doctor to certify as to his fitness or unfitness for removal, and in the event of his having to furnish certificates to the Board, as called upon to do in this instance by the Relieving Officer, would he be allowed postal expenses.

The Chairman said the Relieving Officer, (Mr. Lewis) would be obliged to give a written reply to Dr. Carey's letter, so that both might be placed on the minutes.

Relieving Officer—I received, some time ago, instructions from the Board in all cases of provisional relief to produce a medical certificate each week.

Mr- Fitzmaurice did not thiik it was open to relieving officers to issue red tickets merely to ascertain if parties were fit to be removed or not.

Relieving Officer—I could not tell whether he could be removed or not.

Mr. Fitzmaurice—A red ticket is only issued in cases where patients are unable to attend at the Dispensary.

The Relieving Officer said in this case, when the man's wife came to him, he asked her was he sick, and she said he was. It had always been the practice when application was made for out-door relief for the relieving officer to visit the case, and if he had any doubt as to whether the party could be removed, to issue a red ticket for the doctor's attendance.

Mr. Fitzmaurice said he did not think it was open to him to issue red tickets under these circumstances.

Relieving Officer Codd—We require the medical certificate as to the fitness of the party to be removed.

Mr. Fitzmaurice thought they should not issue a ticket except they believed the patient unable to be removed.

Clerk—Was the man in bed when you visited him?

Relieving Officer—He was not. I generally visit when they don't expect me. His wife met me at the door and

said her husband was just after getting up, and when speaking to him he said he could neither stay in bed or up, as he had an impression on his chest, and was afraid he would smother in bed, but was not able to be up. After visiting the man I went to Borris, and on seeing the Doctor asked him what was his reason for refusing to certify, and told him I thought it would be well if he would do so by that night's post. He said he would not, and that the man was fit to go anywhere; but it was for the information of the Board that I required the certificate. The doctor is to report on a case as long as the patient is receiving temporary out-door relief.

After some further discussion,

The Chairman directed the Relieving Officer to furnish a written reply to Dr. Carey's letter.

It is most unreasonable and unnecessary to call upon the dispensary medical officer to certify the state of health of a patient in default of the proper inspection by the relieving officer. It is that official's duty to see the case and judge for himself, and he has no right to require the attendance of the medical officer, except in a case respecting which he entertains a reasonable doubt. If, however, such reasonable doubt exists, the medical officer is bound to attend and solve it, for Section IV. of the 21st Article of the Dispensary Regulations says:—"He shall give a written certificate under his hand to the Committee of Management, or the Board of Guardians, or the Relieving Officer, *when called upon to do so*, of the state of health of any dispensary patient attended by him, and of such patient's fitness or unfitness to be removed to any union hospital, as the case may be." It is quite indefensible that the relieving officer should spare himself the domiciliary visit—as he seems to have done in this case—by sending the doctor a red ticket for a patient who may be in active health for aught anyone knows.

FOR AND AGAINST ANIMAL VACCINATION. (a)

By Charles R. Drysdale, M.D., M.R.C.P. Lond., F.R.C.S. Eng.,

Senior Physician to the Metropolitan Free Hospital; Physician to the North London Consumption Hospital; and Consulting Physician to the Farringdon General Dispensary.

Mr. President and Gentlemen,—I have been *tempted to* bring the subject of Animal Vaccination *before this* learned society in order that I might have the advantage of hearing what is thought in the country of the immortal discoverer of vaccination concerning certain experiments which have recently been carried on in a very extensive way in Italy, France, Germany, and Belgium.

At a meeting of medical practitioners from all countries in Europe, which took place in Brussels in September last, I had conversations on this subject with a well-known Italian physician, Dr. Palasciano, of Naples, who devotes a medical journal, edited by himself, mainly to the two subjects of ether anæsthesia and animal vaccination. For some years past, also, I have been cognisant of the existence of that important experiment which is being carried on in Belgium by a very distinguished physician of Brussels; and, when at the International Congress in September last, I had many opportunities of obtaining information about it.

It has seemed to me that the Belgian experiment, which I am about to describe in detail, has excited hitherto far too little attention in this country, whether we consider the possible practical utility of the innovation or the curious physiological facts made known by it. Such considerations may serve as an excuse in bringing this subject once more up for discussion.

(a) Read at the Medical Society of London on the 15th November, 1875. Dr. Routh, President, in the chair.

Historical.—Dr. Palasciano, of Naples, when on a visit to France, at the Medical Congress of 1864, which was held in Lyons, seems to have been the first to make known to European practitioners, foreign to Italy, the experiments on animal vaccination long carried on at Naples. The system, he informs us, was commenced in Naples by Dr. Galbiati, a distinguished practitioner of that city, about the beginning of this century. In the year 1810, Galbiati published a memoir on animal vaccination, wherein he asserted that some diseases were transmissible by vaccination when human lymph was made use of. He partook, it seems, the opinions of his compatriot, Dr. Cotugno, who used to say, "Chi inesta, inesta tutto," "He who inoculates, inoculates everything;" and among other diseases communicable by vaccination he enumerated syphilis, citing four cases in which he asserted he had seen vaccine and syphilis inoculated at once. Galbiati, therefore, commenced the practice of, vaccinating all his patients from young calves; and since this time that practice has been carried out by his pupil Dr. Negri, who has always had at the disposition of practioners in Naples a male or female calf, which was inoculated, and sent from house to house on any day agreed on, when a pustule was incised and the lymph taken, for a payment of five francs.

In August, 1862, at a meeting of the Academy of Naples, Dr. Palasciano moved that the practice of human vaccination should be abandoned, and that of animal vaccination adopted. The objection was made that animals themselves have diseases, the germs of which may be inoculated on man, especially tuberculosis. Palasciano replied to this argument that tuberculosis was not found in the bovine species until the animals had attained a certain age; and that it was, moreover, not nearly so common in that species as in ours.

Dr. Negri, of Naples, was in the habit of inoculating from calf to calf, making use indifferently of males an females, according as either was more easily procurable. On the female calf he inoculated the teats; in the males, the skin of the hypogastric region, generally on one side only. Having well shaved the skin, he made scarifications of the length of 8 or 10 millimetres, at a distance of

some 10-15 millimetres from each other. He then rubbed in the vaccine lymph and covered it with a piece of membrane. On each animal he made at least one hundred scarifications, in order to produce a hundred vesicles. By the fourth day after inoculation he made use of the vesicles, which it was his custom to excise entirely, and then open by scarifying, and afterwards express the lymph on a piece of glass. This practice he kept up for a whole week, carrying the animal to every part of Naples where it was required.

Dr. Lanoix, one of the auditory who listened to Dr. Palasciano in Lyons in 1864, was so impressed by this story that he lost no time in visiting Naples, and after studying there the practice of animal vaccination, he returned to Paris with a heifer, aged nine months, inoculated by Dr. Negri in November 1864. In passing through Lyons, on his way to Paris, this heifer had lymph taken from it at the railway station by Dr. Chauveau, of Lyons, and by Dr. Diday, which lymph succeeded admirably in the vaccination of several children, and of Dr. Diday himself. Dr. Lanoix then proceeded to Paris, where his plan of animal vaccination was examined, and afterwards carried out by Dr. Depaul and other able Parisian physicians, as well as by himself.

Two months later, Dr. Ramirez, of Mexico, then residing in Paris, at the request of Dr. Warlomont, of Brussels, brought to that city a heifer vaccinated by Dr. Lanoix. This was the commencement of that great and remarkably successful experiment on animal vaccination which I am about to narrate, from data kindly furnished to me by the illustrious Professor Warlomont, of Brussels.

The first experiments on animal vaccination made in Brussels proved so fortunate and conclusive, that from the month of April following, the town of Brussels, acting on the advice of a local medical committee, voted an annual subsidy to the new institution ; and the superior Conseil d'Hygiene Publique, in its report of the same month, recommended the Government " to favour, by all means in its power, the foundation of an establishment where the cow-pox could be propagated on heifers."

The Government of Belgium did not suddenly defer to he wishes of these medical authorities ; it desired, before taking a side on the question, that the experiments commenced by Dr. Warlomont should have received the sanction of time, and, therefore, remained from April, 1865, up to the end of 1867, in prudent expectation, leisurely studying the important question submitted to it. In the meantime, Dr. Marinus, in the name of a committee appointed by Dr. Warlomont to watch his experiments, sent in an entirely favourable report in October, 1866 ; whilst Dr. Rommelaere, reporter of a committee instituted by the Société Royale des Sciences Medicales et Naturelles de Bruxelles, concluded, in an elaborate work, upon the validity of animal vaccination, in producing a very large quantity of the finest vaccine lymph. On hearing their reports, several provinces, such as West Flanders, Hainault, and Brabant, encouraged the Vaccinal Bureau of Brussels by subscriptions.

The Minister of the Interior of Belgium then resolved to terminate the examination of the question ; and by a despatch dated September, 1866, he reminded the Academy of Medicine that the question of the regeneration of lymph had already been examined by it. He requested that body, then, to make known to him the conclusion it had arrived at, as to whether there was any necessity for regenerating vaccine ; and, if so, in what way this could best be realised. A committee of the Academy, presided over by Dr. leminckx, was charged with examining the question, and Dr. Marinus, the reporter, submitted the following conclusions to the Academy of Medicine : " The committee is of opinion that the following reply be sent to the Minister of the Interior. 1. The Academy has already recognised the utility and even the necessity of renewing vaccine, and has not changed its opinions on this matter. 2. A really practical method of obtaining this renewal would consist in the extended application of animal vaccination, founded on the inoculation of spontaneous cow-pox upon heifers, on which the products of this inoculation should be unceasingly kept up by the processes recently introduced into science."

After consulting the provincial councils of medical practitioners in Liège, Hainault, West Flanders, Brabant, Namur, &c., and receiving affirmative opinions from six of these medical bodies, the Government of Belgium created what is now called the " Vaccinal State Institute of Belgium " in 1868. This institute had for its object— 1. The renewal of the vaccine lymph at present used, by means of animal vaccination, founded on the inoculation of spontaneous cow-pox upon heifers, on which the product of the inoculation is constantly kept up by the processes recently introduced. 2. The distribution gratuitously to all practitioners in Belgium, and to the Communal Administrations, in places where there are no medical men, who make a written demand for it, of the vaccine matter thus obtained, as well as of humanised lymph, the immediate product of vaccination from the heifer on the arm.

On the 11th July, 1868, the Institut Vaccinal de l'Etat become possessed of heifers vaccinated by means of the products of spontanious cow-pox, discovered in 1866 at Beaugency by Dr. Depaul. This was entirely satisfactory; but another discovery of spontanious cow-pox at Esneux was made by Dr. Petry, and this was then used to inoculate the heifers. The Esneux cow-pox was kept up until the year 1870. From April, 1866, up to April, 1870, more than 4000 infants were vaccinated at Brussels by the Esneux virus, and several thousands of tubes and points of the same lymph were sent out to Belgian practitioners.

On May 1, 1870, this vaccine matter from Esneux, although it had, up to that date, preserved all its qualities, gave place, out of respect for a popular opinion, which sought for the renewal as frequently as possible of all vaccine matter from spontaneous cases, to cow-pox freshly discovered at Vanves, which Dr. Constantin Paul had sent specimens of to the Institute, and which succeeded well.

Professor Warlomont, in his address on this subject at the Brussels Academy of Medicine, in 1868, said : " The cow-pox, so long as it does not quit its birth-place, the heifer, possesses all its activity, whatever be the number of its transmissions, on the sole condition that it be carefully cultivated." In October, 1871, the cow-pox of Vanves was still used. Speaking again on the subject of retrovaccination, he says that many errors are afloat as to the product resulting from human lymph inoculated on heifers. His opinion is not quite made up on this point; but he is certain, contrary to the assertions of other observers, that he has been able to make inoculations with human lymph through a long series of transmissions on heifers, without ever having seen one failure, and still less an extinction.

In order to have always, at the Institute, vaccine for the vaccination of children and of heifers, as well as for sending out, in order also to escape from any unforseen difficulties, two heifers at least are vaccinated every week. It is from these that children are vaccinated, points covered, and fresh subjects inoculated. The ivory points are sent away every evening by the post, so as to arrive regularly at their destination twenty-four hours after the demand for them. The lymph, although dry, is always fresh at the time it is used.

The vaccinifer animals of the Institute are young cows or calves, aged from two to three months. They are chosen by preference with russet or white skin in order not to have to vaccinate a cutaneous surface over highly pigmented, as in black calves, when the evolution of the vesicles is not so easily followed. It is necessary that the animals should be well developed and in good health : if good sense did not suggest this, experience would indicate

it, for such animals do not raise vesicles which are acceptable. This, says Dr. Warlomont, applies peculiarly to the fear of the possible transmission of "charbon" by vaccination; "everyone knows that an animal with that disease will never accept vaccine matter."

(To be continued.)

REPORT OF THE PRACTICE OF THE ROTUNDO LYING-IN HOSPITAL, DUBLIN, FOR THE YEAR 1875. (a)

By George Johnston, F.K.Q.C.P.,
Ex-Master of the Hospital.

The seventh and final year of his mastership of the Rotundo Lying-in Hospital having drawn to a close, Dr. Johnston felt desirous of completing the task he undertook when he commenced his official career, *i.e.*, of giving, in as accurate and impartial a manner as lay in his power, an annual account of the health of the institution, so that a just opinion might be formed of its sanitary state, and a fair conclusion arrived at whether a large maternity was or was not a safe asylum for those poor creatures who found it necessary to seek its shelter. In coming, however, or rather before coming, to a conclusion on this point, it was essentially necessary to take into consideration that in this time-honoured institution, whose reputation extended to all parts of the world, whose doors were ever open to those requiring its protection, patients from all quarters seek admission, many labouring under various affections, both of mind and body, as well as those of their parturient state; some far gone in labour, who, neglected or mismanaged by unskilful persons in their own wretched rooms, sought the benefits of the institution when mayhap they were in a most hopeless, if not a dying state; others with symptoms of fever, or other zymotic complaints apparent, were admitted, being at the same time so far advanced in labour that it would be utterly impossible (without running great risk) to send them to a fever hospital; many, led away by heartless, designing individuals, have been seduced, who, becoming pregnant, and being too modest to bear the observations and remarks of acquaintances in the locality where they are well known, rush into the Lying-in Hospital, that amongst the crowd their shame might pass unnoticed. Those were the essential matters that those when discussing the merits of a large maternity should bear in mind, instead of looking superficially at its death-rate, without taking into consideration the various casualties that such an institution was exposed to, before they brought an unfair accusation against it. For instance, during the past year their casualties (what was meant there by that word was the peculiar conditions in which a patient might be labouring under on admission other than her mere parturient state) amounted to 104, besides 60 cases of seduction. Among the former there were 16 from frettings, either from ill-treatment, deserted by husband, or his death shortly before, delicate from starvation, &c.; 5 from tonsillitis or laryngitis; 6 from pulmonary affections, bronchitis, pleuritis, pneumonia, phthisis, hæmoptysis; 4 cases convulsions; and there were also cases of gastritis, hæmatemesis, diarrhœa, peritonitis, pyæmia, fever, and scarlatina; abscess—1 of the mamma, and one in the neck; cardiac, hepatic, or nephritic disease, rheumatism, syphilitic disease, carcinoma of the breast, making in all 164 cases which were admitted under unfavourable, if not most critical, circumstances, and therefore extremely susceptible of any puerperal affection, quite irrespective of their being confined in an hospital. During the past year—from the 6th Nov., 1874, to the 5th Nov., 1875, inclusive—1,065 patients were delivered in the hospital; 275 were delivered in their own homes; 214 were treated in the wards for female complaints; 2,867 were prescribed for at the dispensary, fully one-half of which were treated in the examination-room for uterine diseases, making in all 4,421 relieved during the year. Of the 1,065 cases of labour, 813 were perfectly natural, *i.e.*, the head presented, the child was born within 24 hours without any artificial aid, or any untoward circumstances occurring, the placenta was expelled by the natural efforts, and there was no post-partum hæmorrhage; 40 were abortions, *i.e.*, the ovum or the embryo was expelled from the sixth week to the end of the sixth month of pregnancy. In two instances the child presented with the upper extremity, and in 37 with the lower. It was considered advisable to deliver in 113 instances with the forceps, in 5 instances ovariotomy had to be performed, and in 4 instances was performed version. Labour was induced in 2 instances. In 11 instances the labour was complicated by twins, in 1 by triplets, and in 4 by convulsions. There were 11 cases of accidental hæmorrhage; 2 cases of placenta prævia; 31 of post-partum hæmorrage—viz., 26 trivial, or comparatively so, and 5 serious; 15 of retained placenta; 4 cases of prolapse of the funis. Chloroform was administered in 100 instances. The mortality in the hospital amounted to 27 from all causes, or about 1 in 38. Now, it was worthy of remark that there were 5 patients confined in ward No. 6 on the same day; 1, in 70 bed, died of scarlatina, which she brought in with her; 1 in 69, bed adjoining, was admitted in fever, with great distress of mind; she was attacked with peritonitis, of which she died. Of the next two bed, 68 was occupied by a woman, her third pregnancy, who went out of the institution quite well. Next to her, in 67, a wretchedly delicate woman, with secondary symptoms was confined in her seventh month; she got an attack of secondary hæmorrhage on the fifth day; notwithstanding, she made a steady convalescence, and was discharged recovered from the effects of her confinement. While in 66 bed was a patient, a primipara, admitted in very delicate health, and fretful and nervous, anticipating the result. She was seized with peritonitis, and died. They must surely conclude from this that there was not anything of an epidemic nature existing in the ward, if so, the intervening patients would have taken it, at least, the very delicate patient in 67 bed. Thus, it appeared that out of the total 27 deaths, 9 of them were cases of seduction, 5 of very great distress of mind; 6 were admitted in an extremely delicate or dangerous state; 3 others were primiparas, some of them suspected of being unmarried; and 4 should have died, no matter where they were confined. Alluding to the question of the use of the forceps, Dr. Johnston said: "There where 113 cases were we considered it advisable to deliver with the forceps, and 83 of these were primiparæ, or more than two-thirds, giving birth to 53 boys, 51 of whom lived; 2 were dead at birth; 30 were girls, 27 of whom lived; 1 was dead at birth. 75 mothers recovered; 8 died, 6 being cases of seduction, fretting; 2 cases of peritonitis; 30 were pluriparæ, in which 16 boys were delivered, 14 of whom lived; 2 were dead born; and 14 girls, all of whom lived. 28 mothers recovered, 2 died, 1 of pleuritis, 1 of fungoid tumour of the uterus, with fatty heart; making a total of 69 male children born, 65 being alive at birth, 4 of whom died; 4 were dead born. Thus, 61 males were saved, and 44 female children born; 43 were alive at birth, 2 of whom died, and 1 was dead born. Thus, 41 female children were saved, making a total of 102 children saved who, in all probability, would have been lost if left to the natural efforts; 103 mothers recovered, and 10 died. The forceps which we at first used were of the straight form, both long and short, generally called Beatty's; but finding on frequent occasions that they slipped, particularly when the head was above the brim, or when it was at all tightly wedged high up in the pelvis, and were consequently inefficient, we were obliged to have recourse, about five years since, to the double-curved variety of Barnes, and we have great satisfaction in saying that the more we employ them the more reason we have to be perfectly satisfied with them, inasmuch as we have proved them to be an instrument both safe, easy in their application, and most efficient in their powers of extraction, and at the same time not compressing the child's head to any injurious extent, and perfectly available, whether the head may be above the brim, in the brim, or in the cavity; in fact, we see no necessity for using any other, as they can be introduced by one experienced in their application as easily, if not more so, than the straight variety in all cases; and, as a proof of their not producing any injurious effect on the child, instances are given in our former reports where it has been born alive and lived, although the force used to draw the head through the contracted strait was enormous, and the length of time occupied by the operation was very great. One case may be mentioned as serving for an example, which occurred in a woman in her ninth pregnancy, where there was an exostosis of the right sacro-iliac synchondrosis, preventing the head from entering the brim, and where it took three-quarters of an hour to extract the child, whose head, when born, presented a depression occupying the prominence of the left parietal bone of over 3 inches long and 1¾ inches

(a) Abstract of a paper read before the Obstetrical Society of Dublin on the 8th of January.

broad, and at least ¼ inch deep. Yet that child, a boy, weighing 7 lbs. 12 ozs., lived, and was carried out by its mother quite lively and well on her being discharged on the eighth day. Now if we deduct the 40 abortions from the total number of deliveries recorded as having taken place in the year, it will leave 1,025, which, divided by 113, the number of times the forceps were used in that period, it will be seen that they were had recourse to once in about every 9 1-11th. Some may cavil at the system we have adopted, but the further we pursue the practice the more we see the advantages arising from it in preventing serious consequences to both mother and child—the mother being saved from lengthened agony, prolonged too often to a serious extent from the effects of exhaustion, rendering her liable to inflammation of the soft parts, with all its direful results, such as sloughing and its consequences, fistula, pyæmia, peritonitis, &c., and the child's life preserved by not allowing it to encounter too long the danger resulting from the protracted pressure, both by the compressing of the head in the pelvis and the evil results of the contraction of the uterus round the child and the placenta, thus cutting off the supply so essential to its fœtal existence. In reply to the objection that has been raised by some—viz., that the forceps is a dangerous instrument, and as a proof to the contrary, I may mention that of the 752 cases that have been delivered within the last seven years, in no one instance was injury inflicted by the instrument on the soft parts of the mother. In fact, by using proper precaution in their application, by bearing in mind the different axes of the pelvis and the condition of the passage and cervix uteri, and by introducing the blades with the greatest gentleness in accordance with the direction of these axes, and by taking every care to avoid catching the points of the blades in the cervix, particularly when it is not quite fully obliterated, and when they are applied by making the traction in the proper direction, *i.e.*, in accordance with the amount of descent at which the head may have been arrested in the pelvis, and by continuing it in the axis of the pelvis your extractive force has brought it to, which latter precaution should be particularly attended to, and as soon as the head has been brought sufficiently forward to the outlet, by withdrawing the blades, as our invariable practice is, and has always been, and completing the delivery in the ordinary way, there cannot be, in the hands of the skilful practitioner, any injury produced. And no doubt whatever exists that such practice tends to the more favourable convalescence of the patient. Now, although far from encouraging or inculcating "meddlesome midwifery," as it has been termed, and no doubt in some instances not without reason, as this practice should never be adopted merely in order to save our own time, it should alone be had recourse to when the life of the mother or that of her offspring is in jeopardy. The more we see of early interference and the benefits arising from it, the more we are induced to persevere in it. It has been insinuated that it is a most dangerous practice, and therefore it would be wrong to inculcate it into the mind of the general practitioner; but although no doubt it would be so in the hands of a careless or unskilful person, should that be a reason, may I ask, why the skilful obstetrician should not adopt a measure attended in his hands with perfect safety, by which the many hours of suffering agony of the mother is spared and the life of her offspring preserved, which, under the peculiar circumstances of the case, would otherwise be endangered, if not altogether lost? It might as well be said you should not attempt to take up the subclavian, tie the external iliac, perform lithotomy, or any other of the operations in surgery, because, forsooth! such would be dangerous or unjustifiable in the hands of the unskilful. We have only to add that it has been, so far as our experience goes, the means of saving many lives, both of mother and child, and therefore we have every reason to consider ourselves not alone justified in the continuance of it, but in also recommending its practice to others. At the same time, while doing so, we warn all, as we have always done the student in the class-room, of the dangers to be avoided in using the instruments, not only in the first stage of labour, but in every case, where, even although the os may be fully dilated, the absolute necessity there exists of using the greatest caution and gentleness in the introduction of the blades, in their application, and when adjusted, in the mode of extraction. Referring to cases of craniotomy, Dr. Johnston said they had to lessen the child's head in five instances before delivery could be effected, three of these cases being primiparæ. He was firmly convinced that in each of these five cases, from the length of time their labour lasted, and the amount of compression the child's head had undergone before the application of the forceps, that they were dead before the attempt to perforate; and in the case where the mother died there could not be a more convincing proof of the innocuousness of the forceps, for though the most extraordinary force was used in the efforts to extract the head, it was found on post-mortem examination that the soft parts were perfectly free, even from an abrasion. As the term "post-partum hæmorrhage" in its general signification was one which mainly depended upon the opinion which different practitioners might form in their own minds as to what it really should be considered to convey—for what in the opinion of one would be passed over as not worthy of entering under the category of hæmorrhage might be considered by another as being a very serious case—in order, therefore, to come to some more definite idea of what was really meant by post-partum hæmorrhage, when speaking or writing on the subject, they had adopted the plan they had done in the last report—viz., of dividing the hæmorrhage in this stage of labour into three degrees: The first degree being where a smart dash of blood, or some draining, might occur, owing, mayhap, to a clot forming in the uterus, often the result of want of proper manipulation or mal-application of the binder, where the pulse was barely, if at all, affected, merely requiring the pressing off of the clot, the application of cold to the vulva and loins, the administration of a dose of ergot, with or without a little wine, and the proper adjustment of the binder, and perhaps, as a safeguard, a pad under it; the second degree, where the pulse was slightly affected, requiring, besides the above, the injection of cold water into the vagina; the third degree, where the hæmorrhage, not yielding to the foregoing means, the pulse became weak and symptoms of exhaustion took place, and they were obliged to introduce the hand, or inject some astringent solution, such as that of the perchloride of iron, into the uterus, administer stimulants, nutrition by either mouth or rectum, not to speak of where the patient became so slow and enfeebled as to oblige the performance of the operation of transfusion. There were ten cases of scarlatina, seven in primiparæ and three in pluriparæ. In two instances the symptoms were apparent at the time of their admission, but they could not send them away owing to their labour being so pressing: both were primiparæ, one of whom died on the fifth day. The other went through the sickness favourably and recovered. The second, a case of seduction, aged 22, was admitted on the 21st of August direct from the country where she had slept the night before. Her labour was natural, and she went on favourably till the third day, when, on visiting her, the face was found to be flushed, but without any fever. At 10 p.m. a rose-coloured rash appeared over her neck, breast, and arms. On the 25th she passed a tolerable night; pulse 116; tongue furred but moist; therm. 102·3°, a red blush covering her chest. At 2 p.m. her pulse 140; tongue moist; therm. 104·3°. Scarlatinal eruption had spread to her body, thighs, and legs, a miliary rash covering the back of both her hands. At 6 p.m. the therm. registered 105·3°. On the 26th her pulse was 132; therm. 102°; tongue slightly furred and moist. The rash seemed fading on her chest and arms, but on the inside of the legs, knees, and thighs it was of an intensely red colour. The throat was somewhat sore. At 3 p.m. her pulse was 144; tongue moist, coated with white fur; therm. 105·4°. At 6 p.m. pulse was 124; tongue same as before; strength seemed good. On the 27th the pulse was 132; therm. 102·7°; tongue slightly furred and moist; throat felt and looked better, a miliary rash covering the chest and neck. The left thigh on the inside was of an intense crimson colour, almost approaching to a purple livid hue, as if mortification was about setting in. She had some sickness of stomach. At 3 p.m. her pulse was 124; tongue loaded but moist; therm. 101·7°. Both thighs on the inside still continued intensely crimson, but did not extend below the knees. Her strength kept good, and she was rather cheerful. Desquamation commenced over her chest on the eighth day. The deep colour of her thighs continued, but she convalesced favourably, and was sent to another hospital on the ninth day at her own particular request, where she perfectly recovered. In order to show that a large maternity was not the focus of zymotic diseases, nor did it engender or even cause the spread of epidemics, Dr. Johnston read a table that had been drawn up as heretofore from the Registrar-General's Report of Deaths in the City of Dublin and its Suburbs, which are divided into districts, three being on the

north side and four on the south side of the river. Now, although that table has been cavilled at by some as being inefficient in proving the point which was required, inasmuch as it did not give the amount of the population of each district, or the nature of the complaint, or class of cases, whether they occurred in children, women in their parturial state, or old people, that deficiency must to a certain extent be allowed, and it was to be regretted that the census statistics did not go so far into detail, and therefore at present it could not be remedied. But at the same time he considered that, though defective they might be, in this particular circumstance what was really wanted was proved by the fact that so many deaths from zymotic diseases took place in a certain district that sent a number of patients coming from amongst those contagious complaints to be confined in the hospital.

THERAPEUTICS: INCLUDING THE PHYSIOLOGICAL ACTION OF MEDICINES.

By W. Handsel Griffiths, Ph.D., L.R.C.P.E.,

Licentiate of the Royal College of Surgeons of Edinburgh; Lecturer on Chemistry in the Ledwich School of Medicine, Dublin; Editor for the *Edinburgh Medical Journal* of the "Monthly Reports on the Progress of Therapeutics"; Corresponding Member of the Therapeutical Society of Paris; Hon. Member of the Ontario and Chicago Colleges of Pharmacy, &c.; Librarian to the Royal College of Surgeons in Ireland.

PREFATORY.

In this series of papers a carefully compiled *résumé* of the present state of the science of therapeutics will be attempted. While the writer will endeavour to do justice to the industry and acumen of foreign observers, he will by no means overlook the labours of his own countrymen. The majority of therapeutists are of opinion that in the present state of our knowledge refinements of classification are objectionable, as being inseparable from error, calculated to mislead, and to prove a positive hindrance in actual practice; a simple alphabetical arrangement will therefore be adopted in these papers. Considerable space will be devoted to the consideration of the physiological action of drugs, but all botanical and pharmaceutical details will be carefully excluded.

ACACIA.

Gum acacia being demulcent and emollient is used to allay cough and irritation of the air-passages, and to soothe irritated conditions of the stomach. Combined with other demulcents and with narcotics, it is often administered in irritation of the urinary passages. Applied in the form of a thick solution it relieves the pain of burns and scalds, and promotes the healing process, probably by excluding the air; the mucilage has also been recommended as a useful application for sore nipples.

Gum is not converted into sugar in the system, and hence Graham proposed it as a substitute for amylaceous food in diabetes. The researches of physiologists would seem to throw discredit on its nutritive qualities. Magendie showed that dogs cannot subsist upon it; but no carnivorous animal can be got to live immediately on a non-nitrogenous diet, and no animal can thrive, or even live for a lengthened period, on a single article of food. Frerichs, Blondlot, and Lehman have ascertained that gum is not acted on by the saliva or gastric juice, and Hammond states as his opinion that, owing to its "clogging" the intestines, it is absolutely injurious as an aliment. On the other hand, it has been asserted that Arabs live almost entirely on gum during the gum season, and Hasselquist affirms that a caravan of Abyssinians subsisted on it for two months. It is stated, moreover, that it enters largely into the diet of the natives of Senegal. As the result of my own investigations, I would certainly attribute to it definite nutritive qualities, for I have experimentally determined that the consumption of two or three ounces of gum daily will enable an adult to do on a less proportion of other food. It has been stated that gum passes through the bowels unaltered, but I have not found this to be the case. Boussingault affirms that, having fed a duck with 50 grammes, he recovered 45 from the excrements. Like Garrod, I have been unable te detect gum in the urine, even after the administration of large quantities.

Gum favours coagulation, and hence is useful in the form of powder in arresting bleeding from leech-bites, from the nostrils, gums, &c.

Viborg, Scheele, and Hertwich found that the injection of small quantities of mucilage into the veins of animals caused disorder of the vascular and pulmonary systems, probably by causing mechanical obstruction in the capillaries. Regnandot had the temerity to inject three drachms of gum dissolved in three ounces of water into the veins of a young man. In half-an-hour he became very chilly, the pulse became small, and he had three liquid stools. The chilliness was succeeded by great heat, and after fifteen hours an eruption appeared on the skin.

ACETUM AND ACIDUM ACETICUM.

When freely diluted, vinegar acts as a refrigerant, and is used to sponge the body in fevers, and as a lotion to sprains and bruises; it is also a useful application to the breasts in cases of painful distension with milk, and to prevent suppuration. Warm vinegar is recommended by Dr. Dewees as an application in the early stages of mammary abscess.

Strong acetic acid acts locally as an astringent and stimulant, and when concentrated it is irritant and caustic. As a local astringent it has been found useful in hæmorrhage from the nose, uterus, hæmorrhoidal tumours, and ulcers, and administered in the form of enema it has quelled hæmorrhage from the large intestine. It has been employed as an astringent gargle in cases of relaxed uvula and tonsils, and oxymel is a valuable adjunct to astringent gargles.

Strong acetic acid, or glacial acetic acid, has the power of removing warts, especially when of a syphilitic nature, and corns, owing to its solvent power over the albumen composing them. As a lotion for ringworm of the scalp, acetic acid is of great service, andwhen diluted it soothes the itching of psoriasis and lichen. Dr. Broadbent proposed to destroy cancerous tumours by injecting acetic acid into their substance; the injection should not be too strong or too frequent, lest phlegmonous inflammation ensue. (*a*) Glacial acetic acid vesicates speedily, and may be used in cases in which cantharides is inadmissible; it gives great pain, however, and is liable to cause troublesome sores. When taken internally, in moderate quantities, at intervals, vinegar increases the appetite and facilitates digestion, being a solvent of all the protein bodies except casein. When taken in excess, however, it seriously impairs the digestive powers, and Morgagni affirms that it causes thickening of the coats of the stomach. It has a tendency to produce emaciation, owing, probably, to its solvent action on the fibrine of the blood, and Haller went the length of recommending it as a remedy for obesity, an advice which has been not unfrequently followed by fatal results. According to some chemists, vinegar, or acetic acid, becomes changed into lactic acid in the system. Vinegar is most injurious to anæmic or chlorotic females, and nursing mothers should carefully abstain from it, as instances are on record in which its employment by the mother induced fatal diarrhœa in the infant. Although vinegar is liable to produce diarrhœa and colic, curious to say, it has been found to relieve the colic of lead-poisoning. Some therapeutists have classed the substances under consideration among the arterial sedatives, and have recommended their administration in hæmoptysis, hæmatemesis, and the sweating of hectic. I have never seen good effects from such a treatment, and a knowledge of the chemical action of vinegar upon the blood would lead me to expect results the reverse of beneficial. Vinegar augments the secretion of the salivary glands, and so assuages thirst; it also palliates the heat of the skin, and for these reasons it has been administered in fever. Its tendency to produce colic and diarrhœa is a serious objection to its use in such cases. Clysters of vinegar have been recommended for ascarides of the rectum.

ACIDUM ARSENIOSUM.

Arsenic exercises a destructive effect on vegetation. It is fatal to all animals, but in different degrees, birds, for instance, being less susceptible to its action than fishes; horses and sheep can take comparatively large quantities with apparently temporary benefit. Applied externally, arsenic acts as an irritant, and caustic, and for the latter purpose is used in cases of superficial cancer. The use of arsenic as a caustic demands great caution, as the absorption of it is liable to cause fatal results. It should be remembered that it is the safer course to employ sufficient arsenic to excite active inflammation, so as to impair the absorptive power of the tissues. The local application of arsenic is at times produc-

(*a*) *Medical Times and Gazette*, Sept. and Nov., 1866.

tive of great pain, to allay which it has been recommended to combine it with opium. Marsden suggests the following formula for an arsenical mucilage for the removal of epitheliomatous growths:—An ounce each of arsenic and gum acacia, mixed with five drachms of water. Each application of this should not cover more than a square inch. In onychia maligna Luke recommends an application composed of two grains of arsenious acid in one ounce of simple ointment. In a paper by Dr. Tholen, in the *Archives für Klinische Chirurgie*, vol. xvii., he records four cases of lympho-sarcoma treated sucessfully by arsenic in the manner adopted by Billroth. On an average, from three to five drops of Fowler's solution were given daily, and about twelve injections of ten drops at a time were made into the tumour during the month.

When arsenic is administered internally in medicinal doses (1-24th—1-10th grain) it is stated to check oxidation and tissue change, and to act as a stimulant to the entire organism. According to Kellner, arsenic increases the power of digesting fat, and decreases the amount of nitrogen given off in the urine, thus assisting materially in the formation of flesh. (*a*) At a recent meeting of German *savants* at Graz, Dr. Knapp brought forward additional and indubitable evidence that in some parts of Lower Austria and Styria the peasants are addicted to the vice of eating arsenic, with the professed object of improving their *physique* and personal appearance. (*b*)

In the treatment of several affections of the digestive organs the internal administration of arsenic has been proposed. It has been recommended in irritative and chronic dyspepsia, in various forms of diarrhœa, and in those peculiar cases of chronic vomiting after food in which there is neither pain nor nausea. It has been recommended in the vomiting of cholera; and Ringer states that a drop of Fowler's solution taken before food will arrest the vomiting of drunkards. In chronic ulcer and cancer of the stomach arsenic will allay the pain and check the vomiting.

If food be present in the stomach arsenic is absorbed by the lacteals, and finds its way to the blood through them; if, however, the arsenic be taken on an empty stomach, it will be absorbed by the veins, and passing into the liver, will be separated with the bile. Arsenic seeks an outlet from the system by the bowels. Mayençon and Bergeret find that arsenic is absorbed and eliminated much more rapidly than antimony, and that sulphurous waters aid in the complete expulsion of the arsenic from the system.

The blood is most probably the seat of the changes on which the effects of arsenic depend; it probably tends to disintegrate the corpuscles and to diminish the proportion of fibrine. When the dose of arsenic is too large, or its use too prolonged, the hæmoglobin of the corpuscles under its influence fixes the oxygen more firmly than in the normal state.

Briquet affirms that arsenical salts exert a directly enfeebling action on the heart, an opinion not shared by M. Sée, who believes that they promote the circulation through the capillaries and cause an increase in the frequency of the heart's movements.

It is more than probable that toleration of arsenic may be induced.

Arsenic seems to exert some action on the respiratory organs, probably moderating the respiratory combustion, thus moderating tissue disintegration and causing an accumulation of fat in the economy. It is a matter of history that the ancients used arsenic for shortness of breath, and mountaineers of Styria extensively employ it to free their respiration. Fowler's solution has unquestionably been productive of good in asthma; and Trousseau recommends for the latter affection cigarettes made with a paper which had been saturated in a solution of a drachm of arseniate of soda in three drachms of water.

It has been asserted that arsenic has the power of arresting the progress of the disease in tuberculous phthisis, and Dr. Moutard-Martin (*c*) relates many cases of pulmonary phthisis, some of which he states were absolutely cured, even at an advanced stage of the disease, and some of which were greatly relieved. Dr. Cersoy, of Laucres, and Dr. Isuard, of Marseilles, write in high terms of the efficacy of arsenic in this disease. The latter author contends that by its local and general action it is at once curative and preventive, and that it retards the evolution of tubercles which are not yet softened, and arrests the development of those which are about to form. (*a*)

I have ascertained by experiment that arsenic has the power of at least checking the progress of tuberculosis artificially induced in rabbits. M. Nonat contends that it is only in those cases in which there is no intestinal complication that arsenic is admissible, and that it must be discarded when vomiting and diarrhœa have set in. He gives it only in cases of well circumscribed phthisis. (*b*)

It has been stated that arsenic has been found in all the secretions except the milk, but I have seen a case in which an infant at the breast was most unmistakably affected by an arsenical treatment which the mother was undergoing; and I have moreover, in a careful series of experiments on the lower animals, determined the presence of arsenic in the mammary secretion.

It is found that in patients undergoing an extended course of arsenic that drug is abundantly eliminated in the urine, and it has been observed that this secretion sometimes becomes albuminous, owing probably to fatty degeneration of the kidney. According to some German writers, arsenic diminishes the excretion of urea.

Dr. Samuel v. Pap (*c*) records the result of his experience of arsenic in the treatment of diabetes. He finds that it decidedly diminishes the secretion of sugar, and in some instances causes it to disappear entirely from the urine. Arsenic is contra-indicated in the more advanced stages of the disease associated with progressing pulmonary tuberculosis. Von Pap gives three drops of Fowler's solution in the twenty-four hours, and gradually increases the dose to twenty drops *per diem*. MM. Devergie and Foville, jun., also testify to the value of arsenic in diabetes. They assume that it acts by opposing the vascular paralysis and by awakening the energy of the vaso-motor filaments of the great sympathetic—in a word, by regulating the capillary circulation in the liver. Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE third meeting of the session was held on Saturday, January 8th, Dr. T. MORE MADDEN, Vice-President, in the chair.

DELIVERY OF A PECULIAR FŒTUS OF FIVE MONTHS' MATURITY.

Dr. KIDD exhibited a rare specimen which had been sent him by Dr. McDowell, of Carlow. It was a fœtus taken from a woman, æt. 28 years, who had been married six years and had three children, all of whom were living, and the youngest was 2 years old. She had not menstruated for the previous nine months. In August last she quickened and had never felt life since. Before Dr. McDowell was sent for the patient noticed a flow of blood, which continued up to the time of his visit. The woman had never miscarried. On examination Dr. McDowell found a withered limb protruding from the os, and in effecting delivery the sensation communicated to his hand led him to believe that the head jerked out of the womb. After delivery there was a slight gush of blood. The fœtus was about the size of a five months' child, and had evidently been dead some time—three or four months, or immediately after quickening. The cord was small and shrivelled, and of the character of the fœtus. It took three-quarters of an hour to dilate the os and remove the placenta, which was encysted, and it seemed as if the placenta had continued to grow, although the fœtus was dead. After the extraction of the placenta very severe hæmorrhage set in, but was stopped by treatment. After delivery the woman's breasts were as large and as full of milk as ever they were in her previous confinements. The woman was making a good recovery. At the time of quickening she was employed as a farm labourer, and it was supposed that the jolting of a country cart—in which

she was carried to her work—over an uneven road had caused the abnormal occurrence.

Dr. GEO. JOHNSTON, late Master of the Rotundo Lying-in Hospital, then read his

REPORT OF THE ROTUNDO LYING-IN HOSPITAL FOR THE YEAR 1875,

which will be found at page 43.

In the succeeding discussion,

The PRESIDENT said they all felt deeply indebted to Dr. Johnston for the valuable and important reports which had from time to time been furnished by him to the Society. They contained some of the most important information on obstetric science in existence. He (Dr. More Madden) expressed a hope that yet Dr. Johnston would present the whole of his reports in a combined form, as they would be most valuable. Dr. Johnston had satisfactorily proved that a lying-in hospital was not necessarily a focus for zymotic diseases of any kind, and had reduced its prevalence in the admirable institution over which he had so ably presided almost to nothing. Having alluded to Dr. Johnston's indefatigable exertions in promoting the useful and important work of the Rotundo Lying-in Hospital, Dr. More Madden said, with regard to the application of the forceps before the full dilatation of the os uteri, he could not refrain from expressing his regret that Dr. Johnston had not modified his views on that subject. He (Dr. More Madden) thought it was a practice which required to be received with caution.

Dr. HENRY KENNEDY said he had been afforded an opportunity of seeing the cases of zymotic disease that had occurred in the Rotundo Lying-in Hospital during the period dealt with in Dr. Johnston's admirable report. He wished this statement to go forth, and it was an undoubted fact, that the great majority of the patients exhibited the symptoms of fever on coming into the hospital. The times that the disease appeared after delivery were most various, in some two or three hours, in others as long as forty or fifty hours elapsed. If there was anything like contagion in the hospital, how could such facts be explained? In reference to the question of mental operation in these cases, it was quite remarkable the effect which the mind had on the subsequent recovery of the patients. If the patients were seduced they were almost certain to lapse into a very serious form of disease.

Dr. DENHAM said that not only the Dublin Obstetrical Society and the profession in Ireland, but gynæcologists over the entire of Europe ought to be indebted to Dr. Johnston for the most valuable reports he had furnished of the Rotundo Lying-in Hospital during the seven years of his mastership. The amount of labour, talent, and fidelity with which those reports had been drawn out excited their highest commendation and praise. (Hear, hear.) He would defy any man or any body of men in the slightest degree to cast an imputation upon the correctness and fidelity of those reports. Although he had neither the time, talent, or inclination to produce such reports during his term of office, which preceded that of Dr. Johnston, yet there were some things in those reports which had verified the views which he (Dr. Denham) had propounded while filling the office. In a discussion which took place before the Society some years ago, he expressed it as his conviction that women came into the hospital with disease lurking in their systems, that the poison remained latent until after delivery, and that then the disease became manifest. He had no hesitation in asserting that in many cases in both public and private practice the women who died of puerperal disease had contracted the disease before delivery, and that it only developed itself afterwards.

Dr. FITZPATRICK considered the progress within the last twenty years with regard to the use of the forceps remarkable. At the period he mentioned the crotchet and perforator were used in cases in which at the present day the lives of both mother and child would both be saved by the employment of the forceps. He was gratified to hear Dr. Johnston state in his report that in every case in which he had had to use the crotchet, and the necessity for it had arisen, that so great pressure had been used, and such an amount of obstruction existed, that the child was already dead. He (Dr. Fitzpatrick) had for very many years recommended the use of the forceps in cases where its employment was really necessary, but he was of opinion that it was an instrument that should be handled with extreme caution.

Dr. KIDD considered that Dr. Johnston's reports had not only served the Dublin School of Midwifery and that Society, but also the cause of humanity. He had given them details as to the way in which midwifery was carried on in the institution so complete as they had never had before. It might be a bold thing to say, but he (Dr. Kidd) ventured to prophesy that never again would they have such a system of reports as those which Dr. Johnston had given them. In conclusion, Dr. Kidd said that, unusual as it was to pass votes of thanks at the ordinary meetings of the Society, he begged to move that the marked thanks of the Society be given to Dr. Johnston for his most admirable and excellent series of reports of the practice of the Rotundo Lying-in Hospital. (Applause.)

Dr. DENHAM seconded the motion, which was passed by acclamation.

Dr. JOHNSTON, in acknowledging the compliment, said that he was put on his mettle in regard to the commencement of these reports, because at the time of his appointment the question of large maternities being foci of zymotic disease was under discussion. He was convinced not alone of the safety of the use of the forceps—if in skilful hands—to the mother, but also to the child. He had no doubt about it whatever.

The Society then adjourned.

Clinical Records.

CASES IN PRACTICE.

Reported by JOHN W. MARTIN, M.D.

Assistant-Surgeon, Mayfield Factory Dispensary, Portlaw.

CASE XII.—*Area of Heart's Dulness Enlarged—Double Friction Murmur heard over the whole Cardiac Region—Natural Sounds of Heart Weakened—Bronchophony, Dulness, and Tubular Respiration in the Left Lung—Recovery.*

T. O. N., æt. 35, by profession a strolling player, presented himself for treatment, March 22nd, 1875, with the following history of his case:—Previous to the present attack he had always been a strong healthy man. He assigned as the cause of his present illness a very severe wetting which he received some six weeks before my seeing him. This wetting was followed by sharp rigors, and acute febrile disturbance, lasting a week. As the feverish symptoms developed themselves they were accompanied by a very severe pain in the region of the heart, which remained constant down to the time of his coming under my notice. This pain was greatly aggravated by any exertion or exercise, and was attended by violent headache, dyspnœa, and a hard racking cough, which caused him great distress. When seen by me for the first time the hearts' action was regular, its impulse weak and diffused, the area of dulness much enlarged, measuring 4 × 4 inches in diameter from the lower border of the third rib, left side, and from the right border of the sternum; the sounds of the heart very weak, especially towards the apex, where the first sound could scarcely be heard. A double friction murmur was audible over the whole surface of the heart, but most distinctly so towards the base. He was very subject to frequent and violent attacks of palpitation. Pulse 120, very weak, and compressible. He also complained of pain and weight in the left side, in the axillary region, in which position there was dulness to percussion, tubular respiration, the respiratory murmur being very weak, and bronchophony; no crepitation present, or pleuritic friction sound; the tongue was clean, the bowels regular, but he complained of great loss of appetite, and a sense of weight and fulness in the epigastric region after meals.

During the first week of his illness he was greatly distressed, being compelled to go through a gymnastic performance every evening for the support of himself and family. As treatment I blistered him freely over the heart, and ordered the following mixture:—

℞ Potass. iodidi, ʒi.;
Tr. aconiti, ʒiss.;
Syrupi, ʒi.;
Aquæ ad ʒviij. M.

℥ Two tablespoonsful to be taken three times a day.

April 12th.—Under a steady continuance of the above treatment the improvement in the patient's health was very marked. Pain in the region of the heart, headache, and palpitation no longer felt; the tendency to dyspnœa much diminished; heart's action stronger, and less diffused; both sounds of the heart distinct, and audible towards the apex, where at first they were scarcely to be heard; the friction murmur, formerly noted, now more distinctly noticeable, accompanying each systole of the heart; the area of dulness much diminished, measuring 2 × 2 inches in diameter. General health much improved. I made the following change in his mixture:—

℞ Potass. iodidi, ʒi.;
Tr. cinchonæ, ʒss.;
Sp. amm. aromat., ʒij.;
Sp. chloroformi, ʒiss.;
Infusi cinchonæ ad ʒviij. M.

Two tablespoonsful to be taken three times a day.

I also ordered a stimulant liniment to be applied to the chest twice a day:—

℞ Oleum dulcis, ʒiss.;
Sp. terebinthinæ, ʒi.;
Sp. amm., fort., ʒi.;
Aquæ ad ʒiv. M.

Liniment to be used as directed.

Upon the 15th of April he left the town with the company to which he belonged. The heart's dulness was reduced to its normal limits, 1½ inches in diameter. The friction sound was becoming much fainter. The heart's impulse was normal, in both force and extent of diffusion. He asserted that he felt quite himself again, capable of any ordinary amount of exertion. I directed him to continue the treatment for some time longer, but have no further notes of his case.

As the use of aconite in preference to digitalis in the presence of weakened heart sounds may appear strange to some, I may remark that I find the former the more useful where there is *acute* inflammatory action producing palpitation. Digitalis is the more suitable remedy for chronic cases of effusion and palpitation.

MORTUARIES.

A DEPUTATION recently waited upon the President of the Local Government Board, introduced by Sir Charles Russell, M.P., to urge the necessity of more powers being given to local authorities in regard to the erection of mortuaries. Among those present were—Mr. J. S. Phillips, (member of the Metropolitan Board of Works), Dr. Rogers, Professor Tennant, Mr. T. F. Blackwell, Dr. Henry Cooper, Mr. Bonsor, &c. With the President were—Mr. John Lambert, C.B., Mr. Lumley, Q.C., and Mr. Fleming. Sir Charles Russell, in introducing the deputation, said that the Vestries had the power to erect mortuaries, but they had no power to acquire sites, and the deputation had to urge that, if the parishes were carefully arranged in "districts" and districted together, mortuaries could be so erected as to suit the convenience of many places, and so save the necessity of a separate one for each. It was requisite, too, that powers should be taken for the removal to a mortuary of persons who were stricken dead in the streets, or drowned, instead of the bodies being removed to a publichouse; and it was as urgently necessary that similar compulsory powers should exist for removing from a "living room" the body of a person who had died from an infectious disease. Sir Charles then introduced Dr. Rogers as one who had given the subject his earnest attention for a great number of years. Dr. Rogers then addressed the President at considerable length, showing that, while the Local Boards were unable or unwilling to erect mortuaries, the Metropolitan Board of Works had declined to take the question up, asserting that the matter was wholly within the province of the Local Boards. Then, when sites were obtained by the authorities, the inhabitants had caused the whole thing to miscarry by opposing the erection of mortuaries. The points the speaker urged were—1, that it should be made compulsory on every local Board to establish a suitable mortuary on a common plan, to be approved by the Local Government Board or Metropolitan Board of Works; 2, that these mortuaries should be in the proportion of not less than one to every 50,000 inhabitants; 3, that powers should be provided for the compulsory purchase of property under the provisions of the Lands Clauses Act, and for enabling parishes or portions of parishes favourably situated for such purpose to combine to form mortuary districts, such mortuaries to be maintained at their joint expense and for their common use; 4, that the medical officer of health, or the Poor-law medical officers, or the relieving officer should be empowered and directed to order the removal of a corpse to the district mortuary in all cases where it was found that the family, at the time of such death, occupied only one room, and in such other instances where it appeared desirable to these officials to direct the same. Mr. Phillips also spoke. The President of the Local Government Board, in reply, said that there was no need for the deputation to dilate upon the subject. He reminded them that the Local Government Board had no power over the vestries, who were the local authorities for the erection of mortuaries, and the only grounds upon which he could receive the deputation on this question were that he had some powers under the Nuisances Removal Act of 1866, which still extended to the metropolis; but he could give no other answer than had been given by the Home Office. The subject occupied his attention last year, but whatever compulsory powers were given, nothing could overcome the prejudice of a neighbourhood against the erection of such places. He promised to confer with the Home Secretary, and added that he knew that some of the London workhouses had not more mortuary provision than they needed. The Shoreditch workhouse authorities had to give notice to the parish of this fact in relation to that workhouse, and, he was informed, proper provision was being made for the parish in consequence.

ROYAL IRISH ACADEMY.

A GENERAL meeting of the Academy was held on the evening of January 10, Dr. STOKES, the President, in the chair.

Dr. STUDDERT, LL.D., read a paper entitled, "An estimation of the Free and of the Albuminoid Ammonia yielded by the Stagnant Water of the Dublin Streets, as compared with the Quantities of those Substances obtained from the Liffey Water after receiving the Sewage of Dublin."

Dr. STUDDERT stated that he had been induced, at the suggestion of the Professor of Chemistry, Mr. Galloway, in the Royal College of Science, Dublin, to undertake a series of estimations of the ammonia yielded by the surface water of some of the streets and squares in Dublin, taking as the standard of comparison the water of the Liffey near where the sewage is discharged into the river.

The examination was conducted in the laboratory of the Royal College of Science. Twenty-nine of these street waters and four samples of the Liffey water were examined. The method employed for determining the quantity of free and albuminoid ammonia was that devised by Messrs. Wanklyn and Chapman. The author said that it might be as well to state, for the information of those not acquainted with the Wanklyn and Chapman process, that under the term "free ammonia" is included not only free ammonia, or that body in combination with acids, but also the ammonia yielded by urea, or other easily decomposable nitrogenous bodies.

The average of *free ammonia* obtained from the four

samples of water from the Liffey was 0·0982, or under 1-10th of a grain in the gallon; the average of *albuminoid ammonia* yielded by the same samples of water was 0·0779, or under 1-12th of a grain in the gallon. The average of *free ammonia* obtained from the 29 street waters was 17 grains to the gallon, which was more than 170 times the average of the river water; the average of the *albuminoid ammonia* yielded by the same samples of street water was 3 grains to the gallon, which was more than 38 times the average of that yielded by the four samples of river water. The amount of free ammonia yielded by three out of the four samples of the river water was under that yielded by any of the 29 street waters, with the exception of the samples collected at Stephen's Green, east and south.

The *maximum* of free ammonia obtained from the Liffey water was yielded by the sample collected at Burgh Quay; it only reached 0·175 grains, or less than 1-5th of a grain to the gallon; whilst the *maximum* of free ammonia from the street waters were those collected at Moss Street and Poolbeg Street; it amounted in these samples to 105 grains the gallon, which is 600 times greater than the river maximum.

The *maximum* of albuminoid ammonia from the river water was obtained from the sample collected at Eden Quay, which yielded 0·098 grains; whilst the worst samples of street water in this respect were those collected at Moss Street, Peter's Place, corner of Adelaide Road, and Lees Lane, off Aston's Quay: these yielded 10, 10·15, and 11·2 grains respectively of albuminoid ammonia in the gallon, or more than 100 times the Liffey maximum. As animal refuse in a river like the Liffey is considered to be pretty fairly measured by 10 times the albuminoid ammonia which it yields, the average of such refuse in the four samples of Liffey water examined is equal to 3-4ths of a grain in the gallon; whilst the average amount of such refuse in the 29 street waters examined is equal to 29 grains to the gallon.

Dr. STUDDERT observed that much of this enormous amount of animal matter in the stagnant waters and muds of the streets of Dublin must, if not rapidly removed, take forms that will vaporise, seems all but certain, as the conditions for spontaneous decomposition are always present. What the effect must be on the people's health who dwell in an atmosphere contaminated by such exhalations, he said, it was not for him to determine; he simply recorded the results of his examination, and he left the conclusions to those medical men who have made this their peculiar study; but he thought that the continued presence of so much dirt in the streets would go far to account for the high death-rate (33 to the 1,000 yearly) lately recorded for Dublin, a city whose situation, other things being equal, might mark it out as one of the healthiest in the empire.

Dr. STUDDERT observed, in conclusion, that the results he had laid before the Academy clearly called for better scavenging, and for keeping the streets in such a state of repair as to prevent them from becoming the receptacles of filth and foul water.

MR. THOMAS, the Deputy Coroner for Middlesex, held an inquest last week on the body of a child, 3 months old, which had been lain upon by the father and mother, and the jury returned a verdict of "accidental death." The deputy coroner said the frequency of these cases was now quite alarming, there being upwards of 300 children suffocated in bed annually in the central district of Middlesex alone. He did not mean to explain it, but he might state that a very large proportion of those suffocations occurred on Sunday mornings. It might occur sometimes from over-indulgence in drink by the parents, and sometimes from the fact of the parents working harder and later on Saturdays.

WEDNESDAY, JANUARY 19, 1876.

THE DEBATE ON ALCOHOL AT THE MEDICAL SOCIETY.

IT has been noticed in the pages of the *Quarterly Review*, in a recent article upon Alcohol, that the general impression among persons living outside of the medical profession is that the members of it are almost unanimous in asserting that alcohol is a food, and that it is extremely valuable as a daily article of diet as well as the great remedy in all diseases of debility. Thus it came to pass that, in an inquiry set on foot by the clergy of the Church of England of the diocese of Canterbury, whilst a host of witnesses, including judges, jail chaplains, workhouse inspectors, policemen, and officers in the army and navy, were examined, and their opinions recorded, not a single medical man was called in to testify to the diseases and miseries caused by the use of alcohol in this country.

If the rest of society considers that all doctors encourage men and women to drink they are in a great mistake, and the sooner they are undeceived the better. We have had to record debates on the value of alcohol which have recently been held in New York, in Brussels, and elsewhere, and we have now to show that, as far as the Medical Society of London is concerned, there seems to be as great a difference of opinion as to the value of alcohol, whether as an article of diet, or as a therapeutic agent, as was found to exist among the speakers in New York and in Belgium.

On the evening of December 20th, Dr. Routh, President of the Society, being in the chair, a paper was read by Dr. Lauder Brunton on the "Physiological Action of Alcohol." This author observed that alcohol in small quantities increases the secretion of the gastric juice, and the movement of the stomach, and thus aids digestion. Although unnecessary in health, it is useful in exhaustion and debility. It increases the force and frequency of the pulse by acting reflexly through the nerves of the stomach. In large doses it impairs digestion by precipitating pepsin

and over-irritating the stomach. It may produce death by shock. After absorption into the blood it lessens the oxidising powers of the red blood-corpuscles. This property renders it useful in reducing temperature. When it is very constantly or very frequently present in the blood it causes accumulation of fat and fatty degeneration of organs. It undergoes combustion in the body, maintains or increases the weight of the body, and prolongs life on an insufficient diet. It is, therefore, entitled to be considered as a food. If large doses are taken, part of it is excreted unchanged. It dilates the blood-vessels, increases the force and frequency of the heart, imparts a feeling of comfort, and facilitates bodily and mental labour. It does not give additional force, but merely enables a man to draw upon his reserve energy. It may thus give assistance in a single effort, but not in prolonged exertion. The same is the case with the heart; but in disease alcohol frequently retards instead of quickening the organ, and thus economises instead of expending its reserve energy. By dilating the vessels of the skin, alcohol warms the surface at the expense of the internal organs. It is thus injurious when taken during exposure to cold, but beneficial after the exposure is over, as it tends to produce congestion of internal organs. The symptoms of intoxication are due to paralysis of the nervous system, the cerebrum and cerebellum being first affected, then the cord, and, lastly, the medulla oblongata. The apparent immunity which drunken men enjoy from the usual effects of serious accidents is due to paralysis by the alcohol of the nervous mechanism through which shock would be produced in the sober condition.

In the debate which followed the reading of Dr. Lauder Brunton's paper, and which proved so interesting to the Society as to lead to the very unusual event of an adjournment until January 10th, 1876, several gentlemen adopted entirely the views of Dr. Brunton. Among these was Dr. Broadbent, who, in a very few words, called attention to the points put forward by the author of the paper, all of which he considered as well made out. It was probably from his complete agreement with all that fell from Dr. Brunton that Dr. Broadbent gave so little of his own experience, which would have been most valuable, as that gentleman is well known to be physician to the Fever Hospital, and the question of the therapeutic value of alcohol in fever is at present exciting much interest at home and abroad.

Dr. C. R. Drysdale had never during his whole life been able to understand why alcohol was to be called a food, as the author of the paper had just done. The doctrines with respect to food were quite precise now-a-days. The milk of mammalian animals was a perfect food, and it contained water, albumen, grape sugar, fat, and several salts, including phosphate of lime. All these ingredients, then, were food; but neither alcohol nor ether were contained in milk, and hence the *onus probandi* of showing that alcohol was a food did not lie with those who objected to that way of speaking of it, but with their opponents. In his opinion, ether and chloroform were quite as entitled to the name of food as alcohol was. The experiments of Maurice Perrin ("Dictionnaire des Sciences Méd.") and of Ed. Smith showed that when alcohol is drunk the excretion of carbonic acid by the lungs is lessened. Hence it is by no means a diet like starch or sugar, although he believed it was slowly burnt in the blood, and probably excreted as carbonic acid eventually by the lungs, after perturbing the system or lowering the vitality and power of the muscular system throughout.

It was injurious to take alcohol in very cold countries, and equally so to use it in the tropics: for though it lowers the temperature of the body by preventing combustion, it tends to remain in the nervous tissues (*vide* Percy) and to disturb the functions of the economy. Alcohol, of course, was unnecessary in health; and yet the enormous consumption of strong beer, containing some 5 or 6 per cent. of alcohol, was all but universal in London, with the effect that an immense amount of gout was caused by it, even among the working men. He contended that physicians, at least, should avoid daily draughts of wine or beer, since it was not worth making the experiment on their own persons how little alcoholic fluid would produce gout in twenty years.

With the majority of the statements made by Dr. Brunton as to the physiological effects of alcohol he agreed; but the deductions drawn by the author of the paper were far more favourable to alcohol as a therapeutic agent than he could endorse. In his opinion there was a silent reaction taking place at present against the doctrines of the late illustrious Dr. Todd, and many, and he was of the number, were now very chary of pouring in large doses of brandy or wine even in fever or in pneumonia. Milk diet was more useful in the vast majority of cases in fevers, he thought, and the conclusion come to by the Congrès Médical of Brussels in September, after mature debate, was that the only case of disease absolutely indicating alcohol was that where it occurred in a person of intemperate habits. Finally, he protested against alcohol being supposed to be a food. He denied it: and the more emphatically because it led to so much drunkenness, disease, and social misery.

Dr. Sansom said that the speech just made by Dr. Drysdale was not to the point. The question was, what is the physiological action of alcohol? and for his part, he entirely endorsed all that had fallen from the reader of the paper. Dr. Sansom pointed out the valuable property possessed by alcohol in lessening the temperature, which was now taken advantage of in cases of hyperpyrexia, whether in fevers or in pneumonia, &c.

Mr. Bartlett mentioned that he had recently been making, in company with Dr. Drury, some experiments upon the behaviour of alcohol when taken into the system, and the way in which it was excreted. The test made use of by some of the earlier experimenters was valuable, but not reliable, because there were several substances in the urine which rendered the solution of bichromate of potash in dilute sulphuric acid green. He had used in his experiments spongy platinum; and had found that there seems to be a certain small quantity of alcohol formed in the system, even when none had been partaken of.

Dr. Symes Thompson also expressed himself as in the main perfectly in accord with the conclusions arrived at by the author of the paper.

Dr. Edmunds said that no doubt alcohol had valuable properties as a therapeutic agent; but he thought enough stress was not laid by the reader of the paper on its per-

turbative qualities, which, in his opinion, made it quite unfit to be classed among substances entitled to the name of food. A food, as he took it, was a substance which nourished without causing disturbance to the functions : but this surely could not be said of alcohol with any truth. The fact too related by Dr. Brunton, that it was extremely dangerous to go to sleep in frigid zones whilst under the influence of alcohol, even in small doses, was well explained by remembering the physiological fact that that substance had the property of warming the peripheral organs at the expense of the viscera, by the dilatation of the small vessels caused by the narcotic effects of alcohol. He held that as a general rule it was better for healthy persons to keep up a tonic condition of the peripheral parts of the body, by maintaining a moderate amount of coolness in them, than to heat the hands and feet, and thus withdraw warmth from the brain, heart, and more important organs. He had often noticed that when reading or writing with his feet close to the fire he could not concentrate his thoughts so well as when his feet were cooler.

These views had a bearing on therapeutics, and he thought that there had been too great a tendency to employ alcohol in the practice of late years, on account of theoretical opinions which were now generally admitted to be erroneous. The debate on the 10th January, 1876, was opened by Dr. Milner Fothergill.

RATIONAL AND EMPIRICAL MEDICINE.

"Cum hæc (*i.e.*, medicina empiricorum et medicina rationalis, &c.) per multa volumina, perque magnæ contentionis disputationes, a medicis sæpe tractata sint *atque tractentur;* subjiciendum est, quæ proxima vero videri possint." Such are the words of the old Roman physician, and we could not help recalling them to mind while we were listening to the long and interesting address which Dr. Broadbent recently delivered before the Harveian Society. We all know how, in that celebrated preface from which the above extract is taken, Celsus describes the difference *of opinion* which prevailed centuries before his time *respecting* the relative merits of the rational and empirical *methods* of studying medicine ; how, in language as lucid as it is terse, he stated all that had been urged by Herophilus, Erasistratus, and others, in favour of rational medicine, and all that those "qui se ἐμπειρικοὺς ab experientia nominant" had to say in behalf of the empirical method ; and lastly, how the Roman physician, without being unduly biased by the doctrines of either school, recognised the claims that both of them had upon our attention, and asserted, as every one has asserted since, that the truth was probably to be found between the two extremes.

More than two thousand years have elapsed since the then small medical world was divided by the rival sects to which we have adverted, and it was not a little significant to hear from an accomplished physician of the present day that the same conflicting opinions still obtain in the profession, and that there are not wanting many eminent men who might be justly classed among the empirics of old. Nevertheless we cannot wonder at this. As Celsus truly observes, medicine was an art before it was a science. With us art is more practical, tangible, utilitarian ; science more theoretical, abstract, and conjectural—the progress of the one comparatively rapid, that of the other remarkably slow. If empiricism has, as few will deny, done much more for the alleviation of human suffering than rational medicine has, we cannot be surprised that many refuse to be guided by anything beyond the narrow and often misleading results of human experience. When, therefore, Dr. Broadbent read, in the course of his address, extracts from a pamphlet in which some of the fallacies of rational medicine were exposed, we were not only not surprised, but thought that there was a good deal of truth in the remarks which were quoted. Notwithstanding the great advancement that has been made in our knowledge of the more hidden causes of disease, and of "morbid physiology" and pathology, *i.e.*, of rational medicine, it will be a long time before we can entirely dispense with empiricism in physic. Empiricism will necessarily be, for a long period to come, a crutch, as it were, on which we must lean until the science of medicine has arrived at that perfect state at which we are all aiming, and to which rational methods only can conduct us. The truth of this observation will be apparent if we reflect what the medicine of the future will be if it ever reaches that ideal state which Dr. Broadbent and others before him, have imagined it capable of attaining. Perhaps, however, the most forcible idea of what medicine must be before it can arrive at the dignity of a science is that which was given by Professor Huxley many years ago. Space will not allow us to quote his remarks in his own felicitous language, but the general purport of them was that, not until we can account for the symptoms of an internal disease—diagnose its nature and pathology—say what means will cure it—explain the *modus operandi* of those means—and do all this with as great precision as the surgeon can account for the symptoms, diagnose the nature, and put to rights a dislocated shoulder,—not until then can we say that medicine has arrived at that state of perfection which would warrant us calling it a science, and to which we all hope it may one day reach. It is evident that before such an idea can be realised the collateral sciences must also have greatly advanced, and that our knowledge of the processes that go on in the healthy body, of morbid physiology, and of the mode of action and uses of therapeutic agents, must have extended far beyond its present limits. But, in the meantime, the practice of medicine cannot stand still. Patients must have their aches and their pains attended to. They will take physic of one kind or another. And we must do all we can to meet the demand, and do what good we can, be it by empirical or by rational means.

But while both the empirical and rational methods of medical research must in some measure go hand in hand, we must be careful that neither is carried to extremes. To found a doctrine, or to receive as a settled truth a pathology which is not in harmony with all we know respecting the causes, the conditions, and the therapeutics of a disease, or when we are ignorant of the natural physiology of the part or organ affected, is as irrational as attempting to cure an affection of which we know little by means that are wholly empirical. The chief obstacles which have hitherto retarded, and still retard, the ad-

vancement of medicine as a science are not confined to the difficulties and complexity of the problems with which we have to deal. Imperfect observation, insufficient data, fallacious experience, the *post hoc propter hoc* method of reasoning, the influence of authority, of prejudice, and of routine, and a disregard of the enormous and undigested mass of information that lies stored up, or rather buried, in our countless medical works and periodicals, have no little influence in increasing the uncertainty and indecision which must in some measure be always an inseparable characteristic of that science, and more particularly of that department of it which deals with prognosis and treatment.

No one who takes an impartial but critical view of the present aspect of medical science can deny that there is a large amount of medical error afloat—error both of opinion and practice—and that, too, in spite of the great strides with which medicine has advanced within the last thirty or forty years. Notwithstanding we have in a great measure thrown off that yoke of medical ignorance and superstition with which the minds of our predecessors were burdened, our opinions and practice are still too much biased by the erroneous doctrines and conventional practices of the past. It is by divesting our minds of all preconceived opinions that some of the greatest triumphs of modern pathology have been achieved, and it is by pursuing the same independent path of medical research that we can hope to give still greater precision and positivism to the science and practice of medicine. It has been well remarked that there are more false facts than false theories in our art, and it is just this accumulation of false facts which is acting as a drag upon the progress which we are endeavouring to make. And herein lies the weak point of empirical medicine, as empiricism opens the door by which a large crowd of such facts gains admission, and is received as indisputable truths, while at the same time it encourages all kinds of dogma, loose observations, and plausible practices, which are not only in themselves a great drawback to the advancement of rational medicine, but also lull us into the belief that we know a great deal more than we really do. This is particularly the case with regard to therapeutics—a department of medicine in which we have most need, but in which there has been the greatest lack, of rational principles to guide us.

We cannot, however, now pursue this subject further. All we can say is that if we look to the past we have much to be proud of—if we look to the future we have much to hope for. An examination of the present state of our knowledge teaches us how much we have still to learn, while a reference to past achievements makes us confident that every year will bring us nearer and nearer to that ideal state of medical science which Dr. Broadbent represented to his audience, and at which we all ought to aim, even though it may never be within our reach.

PHARMACY IN IRELAND.

It will be recollected that, on the completion of the Irish Pharmaceutical Curriculum by the Council, an unofficial circular was issued by two of its members, which was strongly animadverted upon in the *Pharmaceutical Journal*, and was the subject of an official inquiry addressed by the Secretary of the London Society to that of the Irish Council as to whether the statements made in the circular were or were not authoritative. The following reply from the Irish Council was read at the last meeting of the London Council :—

[COPY.]

"Pharmaceutical Society of Ireland,
"6 Kildare Street, Dublin.
"2nd December, 1875.

"Sir,—Referring to your letter of 22nd ultimo, addressed to the President of the Pharmaceutical Society of Ireland, I am directed to state that in it you refer to two circulars, one alleged to have been issued by Messrs. McMaster and Hodgson, the other by Mr. Hayes, 'both of which refer to regulations for examination said to have been issued by the Council of your Society.' As your letter did not contain a copy of either of the circulars referred to, the Council decline to give any opinion upon them ; but I am to add that the Council have not given any directions to Mr. Hayes or Messrs. McMaster and Hodgson to issue any notice or circular on behalf of the Council. With regard to other questions in your letter as to proceedings of the Pharmaceutical Society of Ireland, I am to inform you that under Clause 17 of the Pharmacy Act of Ireland, it is provided that any resolutions and arrangements made under the said Act shall be laid before Parliament, and the Council hope you will find in such Parliamentary Report all the information you may require.

"I am, Sir,
"Your obedient servant,
"HUGH JAMES FENNELL,
"Clerk to the Council, Phar. Soc. Irel.

"Elias Bremridge, Esq.,
"Secretary Phar. Soc. Gt. Britain."

The tone of this communication seems to us to be unbecoming, flippant, and almost discourteous to the English society, and we regret that evidence of an unfriendly temper in the Irish Council towards its British sister should thus early in their association be manifested.

It is not inappropriate to this subject for us to register a protest against the course the Irish Council has adopted towards those who desire to make public its proceedings. The acts and sayings of the English Pharmaceutical Council, and of all similar bodies in England, are, as a matter of course, open to all the world, and, as a fact, are egularly published in the *Pharmaceutical Journal* in full detail. The Irish Council, on the contrary, though performg its functions under the authority of an Act of Parliament, and as the administration of a public body, nevertheless discourages and obstructs all attempts to afford the public (for whom it acts) any information of its doings. It has hitherto refused repeated applications for the admission of press representatives ; yet it allows the publication of pseudo-official reports, supplied no doubt by individual members, which give not only the subject-matter of the debates, but the speeches of the debaters. The entire proceedings of the Council since their inauguration seem to indicate that the collective wisdom of its members is represented less in its acts and sayings than in the peculiar characteristics of one ruling mind amongst them.

Notes on Current Topics.

Drunk or Dying?

How often have we heard this question! and how many more times will it be repeated without either the police authorities or the profession taking any such action as would put a stop to the absurd and deplorable mistakes of which we are constantly reading.

Very recently an inquest was held at Charing Cross Hospital on the body of Mr. James Smith, aged 38 years, who was found by a policeman lying on the pavement in St. James's Street, and who was supposed to be drunk. A stretcher was procured and he was conveyed to a station-house, charged with drunkenness, and placed in a cell. When, after an hour and a half had elapsed, he was visited by the inspector, he was found in a slight fit, and breathing heavily; and when the divisional surgeon was called in, he was at once removed to the hospital, by the resident medical officer of which he was seen about ten o'clock. He was then quite insensible, and remained so till he died the next morning. The *post-mortem* showed that death arose from apoplexy from disease of the brain, and it also appeared that drunkenness could have had nothing to do with the cause of his death.

It is a great pity that something is not done to prevent these blunders being made, especially as some very simple measure might be adopted which would at all events diminish the liability of a dying man being subjected to such treatment as this gentleman appears to have been. It may be that, as the morals of the lower classes improve, the exhibition of drunkenness in the public streets will not be of frequent occurrence, but an untimely attack of apoplexy is a calamity to which we are all liable, and therefore it is imperative that such a misfortune should not be aggravated by indignities that might in most cases be easily prevented. It is, moreover, a subject in the settlement of which we should be particularly interested, inasmuch as one excuse for the police authorities not taking *some effective* means to prevent these mistakes occurring, *is the difficulty* of deciding in some instances whether the *insensibility* proceeds from drunkenness or from disease. We cannot deny that there is often much difficulty in deciding whether the case is one of drunkenness or of apoplexy, but that is no reason why such a scene should occur as that to which we have adverted, inasmuch as, in all doubtful cases, the insensible man should receive the benefit of the doubt. Besides, it should not be forgotten that such deep intoxication as would place any one in the position in which Mr. Smith was found is now-a-days very rarely met with among the more respectable classes of society, and therefore the very fact of a gentleman being found in a helpless condition is *primâ facie* evidence in favour of his suffering from the effects of brain disease rather than from the effects of drink.

Perhaps it would be worth while posting up a notice in the police-station in which the more reliable distinctions between drunkenness and apoplexy were specified, and which might be drawn up by the divisional surgeon, or even by the College of Physicians. At all events, in all doubtful cases, or even in any case, we would insist upon the patient being at once removed to the station in a cab, and upon the divisional surgeon being summoned to see him with as little delay as possible.

Death from Chloral.

A LADY, by name Miss Rowe, died last week from the effects of an over-dose of chloral. It appears from the statement of the servant that she was accustomed to taking large doses of "Hunter's Solution of Chloral" to relieve pain in the stomach. On the day in question she had taken half a bottleful, equal to about 125 grains. Hunter's solution of chloral is said to contain 25 grains of chloral to each fluid drachm, and each bottle bears a label stating that from one-half to a whole teaspoonful may be taken by an adult.

Some of the jury considered that the sale of such a dangerous drug ought to be placed under the same restrictions as poisons.

Chloral hydrate is as much a poison as opium, and ought never to be taken except under medical advice; but this or any other drug may receive a name such as would class it under domestic remedies. Can these as such be patented, like many domestic remedies which contain opium, and then is given by careless and ignorant mothers to members of the family irrespectively, children or adults?

We quite agree with the expression of the jury, that if these drugs are allowed to reach the public, whether patented or not, they should be labelled poison. If such were the case people would be perhaps more chary of administering soothing syrups, powders, and cough lozenges, many of which contain no less than 1-6th of a grain of opium, one dose of which is sufficient to produce death in a child, and even in an adult also, if the kidneys happen to be affected.

The Compounding of Prescriptions.

IN our last we referred to the report of the Sheffield borough analyst, who, in testing a number of chemists in Sheffield in making up prescriptions, found in several cases that they had compounded the wrong quantities. At a meeting last week Mr. Brittain, one of the Town Councillors, urged the health committee to prosecute these chemists, whereupon Mr. J. T. Dobb indignantly charged the borough analyst with issuing an unfair report, which had cast a gross reflection on a band of honest men. He pointed out that the test had only been applied to chemists away from the centre of the town, who were not in the habit of dispensing medicines, and then giving his own opinion as a chemist, and the opinion of Dr. Griffiths, the borough medical officer of health, pointed out the difficulty of analysing, and that it was almost impossible to ascertain the quantity of iodide of potassium when mixed with other ingredients. He demanded that the report should be issued in a better form, inasmuch as in its present state it branded the entire fraternity of dispensing chemists. The report will be reconsidered. The annual meeting of the Sheffield Pharmaceutical Society was held the same evening, when the President spoke in strong terms of the recent report of the borough analyst respecting the prescriptions. Several members of the association also spoke strongly on the

subject, and a resolution was passed stating that the report of the analyst had cast unmerited reproach on the entire trade in the town, while tests were made from prescriptions made up by chemists in the outskirts, who were not often called upon to dispense prescriptions. A memorial will be sent to the Council praying for an alteration in the analyst's report.

Dipsomania.

Dr. Mann (*New York Med. Record*, Nov. 13) has recently read a paper on Dipsomania before the "American Association for the Cure of Inebriates." He mentions how frequent the relation between intemperance and insanity is, and asserts that some fourth of all the cases of insanity in lunatic asylums is caused by drinking. He defines *dipsomania* as "an uncontrollable and intermittent impulse to take alcoholic stimulants, or any other agent, as opium, &c., causing intoxication." He distinguishes this from the condition wherein the individual merely indulges in alcohol from love of it, and only occasionally. Cases of dipsomania should be examined, he thinks, for nervous disease, or for hereditary predisposition. The diagnostic symptom in such cases is the irresistible impulse impelling the patient to gratify his love of drinking. Such patients are unlike ordinary drunkards in that, between the paroxysms, they often dislike all kinds of stimulants, and are in these intervals often active in business. Periodic dipsomania is often hereditary, often runs on to mania, and if not checked, to dementia. In the chronic form, the patient is incessantly under the irresistible desire for alcoholic drinks, and if such patients are to be saved from mania, they must be shut up in some asylum where they cannot by any way get access to drink.

This craving for alcohol is often the result of a lowered vitality or abnormal organic development of the nervous system, hereditarily transmitted to the children and grandchildren of drunkards. The blunted moral preceptions exhibited by many dipsomaniacs is like the perverted moral sense in insanity. In all lunatic asylums we discover patients who exhibit no obvious intellectual deficiency, but whose *morale* is deranged.

Dr. Mann is much opposed to dipsomaniacs being taken into ordinary lunatic asylums, as they are such a numerous class, rapidly increasing too, and most troublesome, whilst they are most annoying and perturbing to the ordinary class of lunatics. They require an asylum adapted specially to their treatment. Most dipsomaniacs, when placed in ordinary lunatic asylums, are constantly demanding privileges which cannot be granted, and complain bitterly of the restraint they are undergoing. They laugh at and torment the other lunatics, being mischievous and undisciplined. Dipsomania is thus far more difficult to manage than simple insanity, and requires more perfect discipline, moral as well as physical. The patients have shattered constitutions, and their nervous systems are destroyed. The digestion is weakened, the appetite impaired, and muscles flabby, whilst the generative functions are in abeyance, and the nutrition perverted. They are prone to all kinds of diseases, because weakened by long continued use of alcohol, which acts as a poison to the system. Thus we find various complications in the various cases coming before us, such as cirrhosis of the liver, gastritis, dyspepsia, albuminuria, epilepsy, &c.

The patient must be placed under the most hygienic influence, and pleasant and cheerful surroundings must be sought out for him. Brain excitement is to be avoided, sleep procured, and he should have plenty of exercise in the open air. Purgatives, anodynes, and hypnotics are all useful as adjuvants, as are also tonics; but good food and plenty of exercise out of doors are the best remedies for the disease. The patients should be encouraged to work in the garden, and amusements should be provided for them. By such means patients may occasionally be sent home, permanently cured of dipsomania.

This is a very favourable view of the case, and we wish that we could say that the experience of British physicians entirely corroborated the conclusions of Dr. Mann as to the probability of many of their unfortunate patients returning home permanently cured. There is a general impression, however, we think, in this country, that dipsomaniacs are about the most incurable of all classes of patients, and that, for the most part, they die or become insane.

Poorhouse Patients and their Accommodation.

How far the double object of providing effectually for the insane poor of Ireland and of economising the rates can be most satisfactorily obtained is a problem of interest and importance, whether it be by the establishment of provincial chronic hospitals for the insane at present in, or from year to year likely to become resident in union workhouses, or by setting apart when expedient a whole or portion of a workhouse in each district or county contained within it for the detention of epileptics, idiots, imbeciles, and the like. The inspectors of lunatic asylums in their late report observe that under existing circumstances the tendency of some boards of guardians is to disembarrass their respective unions of persons who come within the term insane, no matter how trivial their affection may be, but particularly if they give any trouble. They probably think as the lunatic district at large, which comprises at least one county has to meet, through Grand Jury presentments, the cost incidental to an asylum residence, that not only a special saving to their unions is effected by an enlarged area of taxation, but by their taking advantage of the 4*s.* weekly rate in aid, for each lunatic when so transferred, a sum of £10 8*s.* annually, nearly equal to the whole cost of the like inmate of a poorhouse, would be further economised; but this fact should not be overlooked, that not only the difference between maintenance in a workouse and a district institution, about £14 per head, would have to be paid, but that to obviate the inconvenience and risk from overcrowding, the costly outlay on structural additions to meet continued requirements would eventually be entailed on local charges. The guardians of of union B. for example, labour under a fallacy in the supposition that by getting rid of their insane, idiots, epileptics, and the like, they obtain fiscal advantages—forgetful that unions C. D. E. and F. can adopt a similar practice in self protection.

The expediency of instituting some countervailing in-

fluence against the undue repletion of asylums from poorhouses can probably, as the inspectors think, be best upheld by a power of re-removal with the sanction of the inspectors, and on definite certificates to the safety thereof from visiting and medical physicians to these establishments is so clear as to require little comment. They state that they "are satisfied that the permanent utility of the lunatic department will be best consulted by confining expenditure within reasonable limits, at the same time not omitting to watch over the comfort and requirements of all denominations."

Care of Lunatics in Irish Workhouses.

THE inspectors of Irish lunacy in their recent report say that from year to year a progressive amelioration has been noticeable in the condition of the mentally affected in the poorhouses of Ireland who, as a rule, have come to be recognised in a proper light, and made objects of kindly consideration by boards of guardians. They are afforded an exceptional dietary, with animal food from three to six days in the week. Their clothing and bedding are improved, and personal cleanliness more carefully looked after. When the number of insane is large, separate apartments with a paid attendant for each sex is usually provided, or well disposed paupers, encouraged by some additional domestic allowances, are employed, and when grounds or open airing yards are available full opportunity for exercise is afforded. In a few workhouses we have found many of the imbecile and idiotic industriously employed in day-rooms set apart for them and, we not unfrequently learn from both masters and matrons that some of them are the most useful and willing of the inmates.

The aggregate of individuals of both sexes in the four districts just named reaches 1,260. The difference of 1,880 in the total of 3,140 becomes divisible among the other eighteen districts, comprising between them twenty-six counties and 118 workhouses, to each of which latter, if equally apportioned, 16, be they idiots, imbeciles, demented, or epileptics, would be chargeable.

Vital Statistics.

DURING last week 6,149 births and 3,892 deaths were registered in London and twenty-two large towns of the United Kingdom. The mortality from all causes was at the average rate of 25 deaths annually in every 1000 persons living. The annual death-rate was 23 per 1000 in London, 26 in Edinburgh, 31 in Dublin, and 32 in Glasgow.

At the request of the municipal authorities, Brighton and Plymouth have been added to the list of towns for which vital statistics are published in these returns. The sanitary condition of Brighton, as the most popular of holiday and health resorts, and of Plymouth, as an important port and the site of one of her Majesty's dockyards, is of far more than local interest. The population of the municipal boroughs of Brighton and Plymouth is estimated, to the middle of 1876, at 100,632 and 72,230 persons respectively.

The population of the twenty largest English towns, estimated to the middle of the year, is 6,953,639. Similar facts are published relating to the "outer ring" around registration London, the population of which is estimated at 797,179. Edinburgh, Glasgow, and Dublin, weekly figures for which are supplied by the Registrars General of Scotland and Ireland, contain an estimated population of 1,074,956. Thus the weekly return will henceforward embrace information relating to twenty-three of the largest cities and towns of the United Kingdom, having an aggregate population (including the London outer ring) of 8,825,774, or little short of nine millions.

The annual rates of mortality per 1000 last week in the other large towns were :—Brighton 13, Sunderland 16, Plymouth 17, Norwich 18, Nottingham 21, Bradford 22, London 23, Hull 23, Leicester 23, Bristol 25, Portsmouth 25, Sheffield 26, Birmingham 27, Wolverhampton 27, Leeds 28, Newcastle-upon-Tyne 29, Oldham 29, Liverpool 30, Manchester 30, and Salford 37. The annual death-rate from the seven principal zymotic diseases averaged 4·2 per 1000 in these towns, and ranged from 0·6 and 0·7 in Norwich and Plymouth to 6·8 and 7·0 in Salford and Sheffield. Scarlet fever is still fatally prevalent in Bristol, and the deaths referred to enteric fever in Sheffield were still more numerous than in recent weeks.

In London the 1,526 deaths included 83 from scarlet fever, 30 from different forms of fever, 20 from diarrhœa, and not one from small-pox. The deaths from scarlet fever were somewhat more numerous than those in the previous week, and exceeded the corrected average weekly number by 25 ; no less than 36 occurred in South London.

The Management of Private Asylums in Ireland.

DURING the year under review, in their recent report, the inspectors state that private asylums in Ireland on the whole have been satisfactorily conducted, and their inmates kindly and considerately treated ; they have to record no case of harshness or personal neglect on the part of proprietors or attendants, neither are they aware of an instance —indeed one could not well occur from the frequency of their visits, and the uncertain periods at which they are made—of an unwarranted detention.

The cases admitting of doubt were mainly those where moral perversities combined with eccentric conduct, but without the display of actual delusions indicated mental aberration, a lengthened indulgence in alcoholic drinks, or the excitement attendant on a continued dissipation, particularly when a predisposition to insanity existed constituting the immediate cause of disease.

It is very embarrassing to deal with such patients ; in confinement they profess deep regret for the past, moralise on the future, acknowledging their error with plausible engag ements to avoid, when at liberty, previous habits. Set free a different story too often has to be told ; they become in a brief period incorrigible as before, unmixed sources of personal apprehension and anxiety to their immediate relatives—not alone among men but females an inebriate propensity with its train of domestic evils is to be found ; the inspectors have known individuals of the latter sex to be admitted from three to four times into licensed asylums.

The Healing Element in Arnica.

THE ingredient in arnica long supposed most important was *arnicine*, an amorphous bitter substance, almost insoluble in water, but freely soluble in alcohol and ether; or else the ethereal oil, which is also insoluble in water. For a variety of reasons, says the *Philadelphia Reporter*, it is now probable that neither arnicine nor the oil, but *trimethylamine*, an organic alkali, is the really useful constituent of arnica.

Trimethylamine, $C_3 H^9 N$, is a clear, colourless fluid, very volatile, and freely soluble in water, alcohol, and ether.

For external bruises and cuts our contemporary thinks that arnica is undoubtedly very useful; and the mischances that have attended its use have probably resulted from the fact that the tincture, containing arnicine and the volatile oil, has been employed. The infusion or decoction alone should be used, and it would be better to give up employing all liniments and lotions in which the tincture is present.

Clinical Instruction for Women.

THE Board of Governors of the Queen's Hospital, Birmingham, have passed a resolution in favour of ladies being allowed to attend clinical lectures at the institution and of enjoying all the privileges hitherto granted to male students.

Exertion is being made to obtain clinical instruction for women in many hospitals, both in town and country, and doubtless other institutions will shortly open their doors to them, but Birmingham, which has been the first in many reforms, is likewise the first town in England to admit women to a medical education.

The Restraint Treatment of Dipsomaniacs.

IN their last report the inspectors of Irish lunatic asylums refer to the subject of establishing receptacles for dipsomaniacs, which for some time has been attracting public attention; they say, "from personal experience we cannot but think that the question of legislating on it is one beset with difficulties, requiring as it would a line of demarcation between excessive drinking as a vice punishable from its results when there was an infraction of law, or as a pernicious habit leading to morbid affections, and sufficient to justify an unwilling detention or confinement after the immediate consequences had ceased, and the assumed lunatic from abstinence became of perfectly sound mind. The impediment would certainly be not so great in respect to the lower orders without social position or means as it must be with regard to the better and richer classes of the community; drunkenness among the former is treated more as an offence or misdemeanour, among the latter as an incipient malady. Certain it is that while the doors of a public asylum are closed as a rule to the confined inebriate, those of a private licensed house are open for his reception. Furthermore, the disposition of property might be seriously affected by the power afforded to one member of a family, even with the most correct and benevolent intentions, to confine another on the plea of extravagance and drunkenness, as if for example a father or husband was detained against his will by a son or wife, he might subsequently be influenced by vindictive motives in its disposition, for no matter whether placed in an asylum or elsewhere, being of clear understanding, his civil rights could not be ignored."

At best the inspectors believe the recognition by Government of hospitals for voluntary applicants or available for the heads of families in regard to their children, and reciprocally as regards married people, but for definite periods, subject of course to official inspection, and stringent regulations is as much as can be reasonably expected, for after all the true test of lunacy is to be had in delusions, be they of themselves apparent or presumable as legitimate consequences.

The Professorship of Midwifery in the Queen's College, Galway.

BY the sudden death of Professor Doherty, which took place at Redcastle, near Londonderry, from apoplexy, on Saturday last, the Professorship of Midwifery in the Galway College becomes vacant. Dr. Doherty was a Doctor of Medicine of Edinburgh University of the year 1833, and was the first Professor of Midwifery appointed on the foundation of the Colleges in 1850. The emoluments of the professorship are calculated to be about £350 a year.

Admission of Women to the Practice of Pharmacy.

AT the last meeting of the Council of the English Pharmaceutical Society this question was again raised for discussion. The proposed list of Pharmaceutical *Chemist* Members originally included the name of Miss Isabella Skinner Clarke, but before the names were put to the vote,

The Vice-President asked that reference should be made to the minutes of a former meeting, when a similar question arose, the result of which was that the matter was referred to the decision of the next annual meeting, which decided, by a large majority, that ladies should not be admitted to the Society. Under these circumstances he did not think it would be becoming in the Council to reverse that decision without again consulting the members at large.

Mr. Hampson thought the Council was fully entitled to act on its own judgement, and considering that the lady now applying for election had passed the major examination, and intended to begin business in the usual way, he certainly thought she ought not to be refused her rightful privilege.

Mr. Sandford moved as an amendent:—"That the persons proposed for election be elected with the exception of Isabella Skinner Clarke." He said if the Council admitted one it must admit all. and he did not think it was for the interest of the ociety to do so. The lady in question had all the trade privileges which her having passed the major examination entitled her to, but he did not see why ladies should be admitted to membership, or they might some day make their appearance at the Council table.

The amendment was seconded by the Vice-President.

Mr. Brown thought the present case not at all parallel to the former one, seeing that this lady was the first who had passed the major examination, and if the sentiment was so strongly against the admission of ladies to membership it was not very likely that such a revulsion of feeling

would take place as would lead to the election of female members of Council.

Mr. Atherton felt sure that the general feeling throughout the country was against the admission of ladies as members. The question having been settled in 1873, he thought it a pity it should have been brought forward again.

A vote was taken, and there being seven for and six against the amendment (one member refusing to vote) it was carried, and the lady candidate was therefore excluded.

The Profession and the Public Press.

We are ofttimes at a loss to conceive the motives which animate editors of the lay press in their relations with the medical profession. Scarcely a week passes that we do not see a ridiculous paragraph of one sort or another "dressed up" and headed with a title at once damaging to our social status. This misrepresentation first commences with students. A riot never takes place which medical students have not fomented, and if a police-constable loses his helmet, or an apple-stall is overturned, some members of that vicious class from the hospitals are sure to have been seen lurking about in the neighbourhood an hour or two previously. When fully fledged and admitted members of an honourable body the same misrepresentation goes on in the lay press with redoubled vigour. A patient dies under the hands of a quack: forthwith a paragraph goes the rounds of the press—"Manslaughter against a Medical Man." A chemist's assistant takes up the wrong bottle and gives a drug to a customer which is attended with serious consequences. The carelessness of Dr. (!) So-and-so is at once the theme of universal condemnation. In Monday's papers we have the latest illustration of what we complain. Our attention was called to a paragraph headed "Extraordinary Charge against a Medical Man," upon reading which we found that a man had entered a pork-butcher's shop at Henfield, in Sussex, represented himself as a medical man, and offered to prescribe for the wife of the proprietor, who was alone in the shop. The woman protested that there was nothing the matter with her, but the fellow persisted in leaving a box of pills and a draught, and in payment took up a joint of pork and some sausages, and with a polite "good morning" quitted the premises. He was afterwards taken in custody at a public-house, charged, and fined 10s. under the Pedlar's Act. Could absurdity go farther? Yet the leaders of public opinion appear to glory in stigmatising a body of gentlemen rather than inquiring first whether such fellows are among their ranks. Surely the *Medical Register* is cheap enough to be found upon an editor's table; six shillings is not a heavy fee to pay for the truth, and were it ten times the amount the money were better spent than in the publication of libels upon an honourable profession. We do not for a moment impute malevolence to our coadjutors on the lay press, but in honour and justice it behoves them to exercise a little more care, and we are convinced that occasions for such paragraphs as the latter would not often arise.

The Threatened Plague.

On Saturday evening, at the monthly meeting of the Metropolitan Officers of Health, an important paper upon the above subject was read by Mr. J. Netten Radcliffe, one of the medical inspectors of the Local Government Board. Mr. Radcliffe, after tracing the various outbreaks of plague which had occurred, and showing the positive existence of the disease in the lower Euphrates in 1874-5, submitted that we could not too early take into consideration the danger to which this country would be exposed from an extension of freshly-developed plague in the countries bordering the Mediterranean, and the measures which might be desirable to adopt to mitigate the danger. As to the danger, should the plague appear in the Levant, it is hardly possible this country could escape the disease either by the sea route or by way of the Continent. At all events any alarm which the apprehension of its approach might create might be allayed by a knowledge of the fact that the medical officers of health had fully considered, in anticipation, the contingency, and were prepared through their several local authorities to meet it. Taking into consideration the vast changes which had taken place in this kingdom since the last visitation of plague, and the existing sanitary organisation, it would seem almost impossible for plague to get a serious hold upon the country. He had, however, no confidence in the population being plague-proof, and therefore it would be a serious error to rest satisfied with leaving things as they were, but it would be well to consider in advance what measures it would be advisable to take should plague be imported into the kingdom. Amongst the suggestions he would make would, as a matter of course, be to rigidly enforce the Quarantine Act, also the rigid enforcement of the Public Health Act of 1875, such as exists with regard to cholera, especially with regard to our shipping in the Thames, and in the Mersey, even extending to the detention of passengers and goods. He expressed his belief that the local authorities had ample power to deal with sanitary regulations in reference to plague as well as other diseases.

Stimulants in Asylums.

At the meeting of the Metropolitan Asylums Board on Saturday a report was presented from the committee of the Homerton Hospitals as to the extraordinary discrepancy which has existed in the cost of maintenance and length of residence of patients in the Homerton as compared with the Stockwell Hospitals, upon which there has been much controversy. The report stated that they had fully considered the whole subject, and had come to the conclusion that the cost of maintenance of patients and the duration of residence in hospital were matters for which the medical superintendents were alone responsible; they, therefore, called upon Drs. Collie and Gayton to report on the matter. Dr. Collie, in defending his own action, admitted that the difference was considerable, and said it was explained by the more liberal use of stimulants at Homerton than at Stockwell; but the large discrepancy under the head of medical extras had been in consequence of the way in which the tables at Homerton had been constructed by the accountant's clerk. Although admitting the difference amongst medical men as to the use of stimulants, Dr. Collie justified his large administration of stimulants. After showing the impropriety of turning patients out of hospital too soon, so as to breed contagion, he pointed out that if his system is interfered

with the responsibility will rest upon the managers. Dr. Gayton's report was similar to that of Dr. Collie.—Dr. Cortis and other members of the Stockwell Hospitals committee defended the management of that institution. —After a very lengthened discussion the report of the committee was adopted, but not the reports of the Homerton medical officers.

DR. CHARLES A. WEST has been placed on the Commission of the Peace for the borough of Bodmin.

SURGEON-MAJOR DANIEL WRIGHT, M.D., has been permitted to retire from the service on a pension of £220 per annum.

SURGEON THOMAS SEWARD, M.D., on half-pay, late of the 90th Foot, died Dec. 23, 1875. He entered the service, Feb. 1859, and retired on half-pay, Sept. 1873.

A PAUPER inmate of Horsham Workhouse died in the Union on Christmas-day from the effects of gluttony. He attacked his Christmas dinner so ravenously that in a few minutes he was choked.

DR. GEORGE JOHNSON, F.R.S., F.R.C.P., has been elected Examiner in Medicine at the Royal College of Surgeons of England, in the vacancy caused by the resignation of Dr. Wilks.

SIR DAVID DEAS, K.C.B., Inspector General of Hospitals and Fleets, died on Saturday last at the residence of his brother, Lord Deas, in Edinburgh, in the 69th year of his age.

SURGEON-MAJOR ROBERT WILSON, M.D., of the Madras Medical Department, died on Dec. 31, 1875, at Denton House, Elphinstone Road, Southsea, Hants, aged 48. He entered the service, Aug. 1856, and became Surg., Aug. 1868.

WE understand that the Obstetrical Society of London propose to give a *conversazione* in February next, and we believe that permission has been granted by the President of the College of Physicians for it to take place at the College. At the next meeting of the Society, which will take place on Wednesday, the 2nd February, the discussion introduced by Dr. Meadows upon the post-mortem diagnosis of a nulliparous uterus will be resumed, and a number of specimens illustrating the subject will be exhibited by Dr. Braxton Hicks and other gentlemen.

AN inquest was lately held at Paddington upon the body of a gentleman who was taken to St. Mary's Hospital for an injury received to the head, and who died suddenly as the result of the accident. At the inquest it was stated that deceased had a wife living, from whom he was separated, so his property was directed by the coroner to be impounded till the widow or other claimant should prove their right to it. Two ladies now claim to be the wife, so the coroner finds himself in a dilemma from which he can be extricated only by the law.

AT the annual meeting of the Lewes Town Commissioners, last week, it was stated by Mr. Braden, the medical officer, that not a single case of fever had been reported to him during the last six months. At this time last year typhoid fever was very prevalent, and a Government inspector was sent down. Recently the water company have obtained their supply from a new source, and direct from the chalk. The absence of fever is attributed by him to this change, together with the improved sanitary arrangements in the town.

THE total expenditure of the Irish lunatic asylums for the past year amounted to £184,749, and although there were 240 inmates more in these institutions for the time being, the charges were less by £4,060 than in 1873, being at the rate of £25·2 per head, as against £26·4 in the last-named year. The capitation cost varies in different asylums, and the inspectors remark that, as a rule, in consequence of repairs, refitments, and minor alterations to meet contingent wants, that the less perfect in construction and worse furnished the establishment at large, the dearer is after maintenance.

IF Dr. Robert MacDonnell, whose intention to present himself as a candidate for the Vice-Presidency of the Royal College of Surgeons in Ireland at the next election in June we have already announced, should carry that intention into effect, it will be necessary for him to vacate his seat on the Court of Examiners, his retirement taking effect probably from the first Tuesday in *May*, when the election of Examiners takes place. In such case we are authorised to state that Dr. Swan, Lecturer on Anatomy in the School of Steevens' Hospital, will present himself for the vacant Examinership. Dr. MacDonnell is at present the representative of Steevens' Hospital on the Court, and if replaced by Dr. Swan, the Hospital and School will still be represented. Dr. Swan is a Licentiate of the College of twelve years' standing, and one of its Fellows since 1868.

Correspondence.

THE ASSUMPTION OF MEDICAL INITIALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to draw your attention to the fact that of late some schoolmasters and others engaged in tuition have been placing after their names in advertisements the letters M.R.C.P. London. As these gentlemen have no connection whatever with the College of Physicians, or with the medical profession, is not this a breach of the Medical Act?—is it not falsely using initials leading the public to suppose that they are registered under the Act?

On making inquiries I find these gentlemen *qualify* for what they call the M.R.C.P.L. by passing an examination at some *institution* in London named the College (Royal) of Preceptors. The examination is, I believe, accepted as equivalent to the *matriculation* by some of the medical bodies in Schedule A.

Now if the assumption is not a breach of the Medical Act, is it not an easy way of obtaining a bogus distinction? Why go to Philadelphia for a degree which is only (if at all) of use to enable him to use *falsely* initials to which he has no legal right, when he may obtain authority to use the initials of a first-class British medical diploma without any medical training whatever.

I think the London College of Physicians is much to blame

in allowing this assumption, calculated as it is to bring their diplomas into contempt.

I hope you will allow this communication a place in your columns, as the habit is increasing. In one of the Cork newspapers last week I saw the advertisements from two M.R.C.P.'s.

Yours faithfully,
L.R.C.P.

THE NEW GRADE OF IRISH PHARMACEUTICAL CHEMISTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly state in your journal if there will be any check (and if so, what the nature of it may be) on the new grade of Irish pharmaceutical chemists, preventing them from *prescribing* in their establishments, a system which would be alike dangerous to the public as well as injurious to medical practitioners.

I am, Sir, yours truly,
MEDICUS.

[The Pharmacy Act declares that pharmaceutical chemists shall not be entitled to perform the functions of medical practitioners. This restriction, however, does not, as a matter of fact, prevent the similar class in England from prescribing in very many cases, nor does any law which now exists prohibit any person from practising medicine so long as he does not pretend to be a duly qualified medical practitioner. In fact, the pharmaceutical chemist will be legally disentitled to prescribe, but will actually be in the same position as any other person to infringe the law.—ED. M. P. & C.]

THE MEDICAL COMMISSIONERSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

ALTHOUGH the resignation of Dr. John MacDonnell is nearly three weeks old, no appointment to the office of Medical Commissioner on the Local Government Board for Ireland has yet been made, and the intentions of the Lord Lieutenant as to the succession are yet unknown. The impression within the profession is that the selection lies between Dr. Macnamara and Dr. Croker King, the choice of the former being indicated by the general voice of the Poor-law medical officers and the profession, that of the latter being suggested by political report and by an experience of the circumstances which control such appointments in Ireland. Speaking generally, and without at all applying the observation to the candidature of Dr. King, we may say that from a medical aspect it would be nothing less than calamitous that an incompetent, inexperienced, or inactive officer should be put in charge of this, one of the largest and most onerous of the Irish public services. The appointment is not one of those obscure legal sinecures to the occupancy of which the public may be and is absolutely indifferent, and the election to which excites only place-hunters and hungry members of Parliament. There is something to be thought of in the choice of a successor to Dr. John MacDonnell other than the distribution of a political plum to one fortunate claimant from a host of greedy and open-mouthed gapers each of whose relatives have deserved well of the Government. In this case there are a thousand officers to be watched and controlled, a hundred and sixty-three boards of guardians and nine hundred dispensary committees to be kept straight in their medical business, a hundred and fifty thousand a-year to be expended, and nearly a million of sick poor to be cared for, and in such circumstances the claims of petty patronage ought to stand aside, and those of merit should come to the front. We proclaim most earnestly the feeling of the medical profession that such interests cannot be fairly entrusted to a lay oligarchy, even if supported by the dictum of a medical subordinate. The Medical Commissioner of the Irish Local Government Board should be a man who is conversant with the service, and who, in addition, possesses the judgement, force, and professional rank necessary to give effect to his views. In the person of Dr. Macnamara these qualities are known to exist, and professional feeling in Ireland distinctly indicates its approval of his candidature, and its great apprehension lest personal and political influences should inflict upon the Poor-law Medical Service the incubus of a ruler whose only quality may be that he has opportunely made room for some nonentity whose advancement was desired. There are rumours that influences are hard at work in this latter direction, and we would suggest to the Government that a family job of this sort in the selection to so important an office would be most unpopular, not only with medical men, but with those of the public who knew anything of the matter.

THE election of a medical officer of the City of Dublin Hospital in the room of Dr. Arthur Barker, who was elected to an appointment in University College, took place, after a lapse of several months, last week. There were several candidates—Dr. Arthur Macan, Assistant-Physician to the Rotundo Lying-in Hospital; Dr. Wm. J. Smyly, Demonstrator of Anatomy in the Irish College of Surgeons; Mr. Roe; Mr. Hercules McDowell; and Dr. Wm. Stoker. Within the last year the system of election, which had previously lain in the hands of the medical officers solely, had been changed, and the monetary responsibilities of the hospital being assumed by the Board of Governors, they were invested with a voice in the choice of the medical staff. That to which we refer is the first election held under the new system. Three of the names which we have given above were selected by the medical officers and recommended to the "General Board," by whom Dr. Macan was selected to fill the vacant physiciancy. Dr. Macan is, it will be observed, a pure obstetrician, and his election restores to the City of Dublin Hospital the midwifery element which was contributed to it for so many years by the late Dr. Beatty. We understand that a special ward will be henceforth set apart for obstetric cases, and that this department will be made a special feature in the education of students of the hospital. Dr. Macan holds his qualifications from the University of Dublin of the year 1868, and became Assistant-Physician to the Rotundo Hospital in 1873.

A CASE which will raise a very important medico-legal question is about to come before the Master of the Rolls in Ireland, in the form of an application by the National Insurance Company to set aside an insurance upon the life of one of its policy-holders. This insurance was effected some years since, the health of the policy-holder being then duly certified as good; but since then uncontrollable intemperance is said to have taken possession of him, and more than one attack of delirium tremens has been the result. In anticipation of claim upon the company before long, its directors are about to apply to set aside the policy. If it be not alleged, or if the allegation be not proved, that the intemperance existed as a habit at the time of insurance, and was concealed (a circumstance which would, of course, nullify the policy at once), the case will raise the question whether a person who insures his life and then deliberately embarks in habits of drunkenness can claim the fulfilment of the contract on his death. In other words, it will have to be decided whether dipsomania is to be legally regarded as a disease which is outside the control of the victim of it, or whether it is a vice which he deliberately pursues, and which ought not to be included amongst the risks incident to the life of a healthy person.

WE learn with satisfaction that Dr. Lyons, of the Dublin Catholic University and the Richmond Hospital, whose state of health has for several months caused much anxiety in the profession, is almost entirely restored to health, and has returned to Dublin to resume his practice.

Literature.

MEDICAL POLITICS. (a)

THERE are men who believe firmly that the institution of prizes for essays on particular subjects stimulates public opinion. The late Mr. Carmichael was one of those; and he munificently left the sum of 3,000*l.* to the College of Surgeons of Ireland, in order to found a prize of 200*l.*, and a second of 100*l.*, every fourth year, the subjects to be selected for competition being limited to three. They are—1st. The State of the Medical Profession in its different Departments of Physic, Surgery, and Pharmacy in Great Britain and Ireland at the time of the writing of the prize essays; 2nd. The State of the Hospitals and Schools of Medicine, Surgery, and Pharmacy; and 3rd. The State and Mode of Examination, or of Testing the Qualifications of Candidates of the different Licensing Colleges or Corporations in Medicine, Surgery, and Pharmacy." Some directions are given in the will as to what points the testator would like the writers to attend to; and as to the publication of the successful essays so as to bring them prominently before the notice of leading members of the profession, Mr. Carmichael's object is the improvement of the profession, "with the view of rendering it more useful to the public, and a more respectable body than it is at present." These outspoken and not too complimentary expressions tell us how strong was the feeling of the testator about his profession; and his handsome legacy ought to do something towards furthering the object he had so warmly at heart.

The present essay is a neat, well-printed little volume of attractive appearance. As to its contents, we will take them in the order of the writer, so as to give the clearest impressions as to his method of handling his subject. His two leading principles are organisation or co-operation for the mutual benefit of the co-operators, and the right of self-government. As to the present position of the profession in these respects, the writer thinks it "for all practical purposes a disorganised rabble." He puts some home-truths in graphic language of unmistakable purport, and evidently holds with the late Mr. Carmichael, that there is much in the profession that might be improved. But that any metropolitan physician makes 30,000*l.* per annum is surely taking too rosy-hued a view of the prizes of practice. The question of a species of trade combination to prevent overstocking the market by limiting the number of entries into the profession is next discussed, amidst some generalisations in supply and demand. Drug selling is condemned. The fitness of women for the compounding of medicines is asserted with fairness, and this leads to the consideration of the higher education of women. The writer holds that lady-doctors are desirable, "on behalf of the young unmarried woman suffering from disease that nothing would induce her to speak of to a gentleman practitioner," a view which many will feel inclined to challenge. Women would sooner tell a man of many little matters of a personal character than trust them to another woman! Then follow some considerations as to the necessity for trades unions, and it is held to be necessary for the profession to combine. The different associations of medical men are next reviewed, and their aims and their aspirations given. Then follows the Poor-law Service of Ireland, and the dispensary system, which seems to need some amendment. The inefficiency of the preliminary examinations of the Irish corporations is dilated upon, apparently not unnecessarily; after which comes something very like an introductory lecture when its subject-matter is the course of study to be pursued.

Some decidedly pertinent remarks are made as to examiners and lecturers, and as to how both might be improved. Conjoint schemes of examination are themselves examined. After that comes the after-education of the individual himself, certainly by far the most important matter of all education.

Such is the scheme of the essay. As to its real value, probably differences of opinion may be expressed; it certainly ought to produce some good effect. Possibly if the style was a little more attractive and the sentences shorter and more incisive, the impression produced would be more vivid and distinct. Take, for instance, pp. 84-5, where three sentences cover one page and a-half. It is not that Dr. Ashe's writing is unreadable by any means, but that it does not produce well-chiselled impressions, so desirable in a work of this character, that makes us feel critical. The subject-matter refers almost exclusively to Ireland, as might be expected.

It is very desirable that the profession of medicine should become more conscious of what its true position ought to be. There is, doubtless, as Dr. Ashe states, much to be desired in the matter of improving examiners and teachers as well as students. Merit is too often subordinated to nepotism, to private friendship, and to other considerations, which ought not to be subordinated to it. Vigorous expostulalion on these matters can but evoke an affirmative response from the profession. All thinking members of the profession fully realise how very desirable it is that our profession should not only occupy a higher position in public opinion, but that it should so purge itself that its claims to such recognition are better justified and therefore less incontrovertibly than is at present the case. Dr. Ashe possesses the spirit of Carmichael, and we wish all success to this initial essay, which, on the whole, deserves well of the profession.

(a) "Medical Politics." Being the Essay to which was awarded the First Carmichael Prize of the Royal College of Surgeons of Ireland, 1873. By Isaac Ashe, M.D., Physician Superintendent of the Londonderry District Hospital for the Insane. Fannin and Co. 1875. Pp. 174.

Medical News.

St. Andrews Graduates' Association.—The following officers have been elected for 1876:—*President of Council*, Benjamin W. Richardson, M.D., F.R.S. *Honorary Treasurer*—Dr. J. H. Paul. *Honorary Secretary*—Dr. Leonard W. Sedgwick. *Members of Council*—Drs. W. Bloxam, W. Cholmeley, T. B. Christie, J. Lockhart Clarke, W. F. Cleveland, W. F. Coles, George Cordwent, Edwards Crisp, T. B. Crosby, W. H. Day, Henry Day, T. O. Dudfield, S. Day Goss, J. T. Griffith, J. Bower Harrison, Samuel Hill, C. Holman, Wharton P. Hood, J. Hughlings Jackson, S. Lawrence, J. Murray Lindsay, J. A. Lush, John D. Macdonald, J. Macintyre, Henry Moon, Richard Norris, R. Budd Painter, C. Royston, Joseph Seaton, R. H. Semple, J. Sparshall Willett, E. F. Watkins, W. Rhys Williams, A. Wynn Williams, A. Wiltshire, W. Bathurst Woodman, Mr. James Menzies, M.A., and the Rev. Charles Rogers, LL.D.

A Protest against Vivisection.—We hear that Baroness Burdett Coutts has written to the Archdeacon of London, asking him in his official capacity to invite the clergy to satisfy themselves at what hospitals vivisection is still practised, so that they may not preach for institutions where such abhorrent cruelties are sanctioned.

Testimonial to Mr. George Tatham, of Brighton.—A massive silver salver, with an appropriate inscription, was presented last week to Mr. George Tatham, who enjoyed considerable repute in Brighton, on his retirement from practice, which extended over thirty years. Only ladies, former patients, were allowed to subscribe, a cheque for twenty guineas from a gentleman being returned. Mr. Arthur H. Cox, one of the borough justices and late mayor, acted as treasurer.

Means of Transporting Invalids.

THE use of hammocks, or swinging beds, for the comfort of invalids who are obliged to move from one place to another, should become more general. By proper spring adjustments at the two ends, the patient may escape all shock or jar. A freight car may be engaged, or, if the cost of the journey can

be borne, a palace car. Such a low frame as is used for a child's suspended crib could be used. Perhaps a crib on springs, without the swinging or rocking feature, would be better still than a cot. Twine hammocks for the purpose are manufactured in London. The points of suspension are nine or ten feet apart, and the patient is placed in it with the feet toward the engine.

Inoculation of Varicella.

PROFESSOR STEINER, of Prague, has lately performed inoculation of varicella in several cases, and has arrived at the following results: The experiments were undertaken in consequence of the opinion being still held by some that varicella is only a modified form of variola. 1. The contents of the varicella vesicle are inoculable. Of ten cases of inoculation, eight were successful, and two failed. 2. After inoculating varicella, varicella, and not variola was always produced. 3. In all the children that were successfully inoculated, the stage of incubation was eight days. 4. In four cases, the general health of the children remained unchanged during the period of incubation, and the eruption of varicella vesicles appeared suddenly, without any premonitory stage. 5. In four cases, a distinct prodromal stage, of four days' duration, was observed; the symptoms being, rise of temperature and increased frequency of pulse, with distinct exacerbations in the evening and remissions in the morning, restless sleep, dulness, loss of appetite, and redness of the mucous membrane of the mouth and fauces. 6. The greatest rise of temperature—when it occurred—generally coincided with the eruption. 7. Defervescence was generally rapid and complete; intercurrent rises of temperature in rare cases attended the appearance of fresh vesicles. 8. Vaccination had no influence whatever on the form of the exanthem. Of the eight children successfully inoculated, five had been vaccinated, and three had not. 9. Varicella does not protect from variola. Dr. Steiner saw a child die of confluent small-pox fourteen days after an attack of varicella.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ROYAL INSTITUTION.—On Friday evening next, at 9 o'clock, Prof. Tyndall will lecture "On the Optical Deportment of the Atmosphere in relation to the Phenomena of Putrefaction."

SIR JAMES PAGET, Bart., will deliver the Hunterian Oration this year.

A HANGMAN'S REFRESHMENTS.—In connection with the recent execution at Dumbarton, Mr. Grant, the Governor of the prison, says the *Glasgow News*, has sent in an account to the Dumbarton Town Council for the "refreshment" of Marwood during the three days he was resident in the prison on the occasion, among the items in which are "one bottle of brandy, one bottle of whisky, and one dozen of bitter beer," being a bottle each for the first two days, necessary, no doubt, to fortify him for his disagreeable work on hand, and a dozen of "bitter" for the third day, as indicative of his state of feeling after all was over. There was also a charge in the account for "one bottle of brandy, one bottle of whisky, one bottle of sherry, and one bottle of port," said to have been used on the morning of the execution. As Mr. Grant had no authority from the magistrates to incur any such expense the Council refused to pay the account, and remitted the matter to the treasurer for inquiry.

SURGICAL SOCIETY OF IRELAND.—The next meeting of the Society for the present Session will take place on FRIDAY evening next, the 21st day of January, 1876. Chair will be taken at half-past eight o'clock, precisely.
By Order,
B. WILLS RICHARDSON, F.R.C.S.I., }
JOLLIFFE TUFNELL, F.R.C.S.I., } Hon. Secs.
Royal College of Surgeons, December, 1 75.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. FIRST or PRIMARY PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination will commence on MONDAY, FEBRUARY 7th. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.
SECOND or PASS EXAMINATION for the LICENCE.—The next Examination will commence on MONDAY, FEBRUARY 14th. Gentlemen who have completed four years of Professional Study according to the College Regulations are eligible for admission to this Examination.
Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under special By-laws.
Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the By-laws are to be left at the same time.
The Licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Poor-law Board as a qualification in Surgery as well as in Medicine.
Pall Mall East. HENRY A. PITMAN, M.D., Registrar.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.
PATRON:—H.R.H THE PRINCE OF WALES.
This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.
To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.
The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.
Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.
Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.
Each donation of Five Guineas gives the donor a life-vote.
Annual Subscribers are entitled to one vote for each half guinea paid.
An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.
Full particulars as to the working of both Institutions, terms, &c., can be had at the office, 40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.
No Commission charged to Purchasers.
Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in *Dr.* Langley's List, which is sent post free on application).

A 15. BRITISH INDIA. Partnership in a well established Practice, realising £2,500 a year. The Junior should be doubly qualified and competent to speak French, German, or Italian. A Half Share is offered with Succession to the whole in the course of a few years. The greater part of the premium may be paid by instalments, but no gentleman need apply who has not £500 at command.

A 16. NEW ZEALAND. Partnership with Succession, with preliminary "Locum Tenens" engagement *if desired.* One of the oldest practitioners in the *Colony,* having a Family Practice in one of the best *towns,* desires to secure the co-operation of a suitable man to succeed to his connection which realises upwards of £1,500 a year. The candidates must possess the Degree of M.D. and a Surgical Diploma, should be married, and have at their disposal £1000. The expenses are small and society pleasant.

A 14. Within 30 miles of London, in a prosperous market town, a good middle-class Practice, yielding over £600 a year. Appointments, £200. Convenient house, centrally situate, with stabling, &c. Rent, 50 guineas. Premium, one year's purchase.

A 13. LONDON SUBURBS. Established 18 years, a Family Practice realising £400 a year, but with great scope for increase. The Vendor being in bad health. Appointments bring in £110 a year. There is an excellent residence containing 14 rooms, with garden back and front, stabling, &c. Rent, £60. To an active gentleman the opening presents a favourable opportunity of getting into Suburban Practice at a small cost.

A 12. BRANCH PRACTICE. £200 a year with great scope for increase. The whole connection is believed to be transferable. Rent, £25. Premium, £100, part of which may be paid by instalments.

A 11. BRANCH PRACTICE near a large town. Receipts, £250 a year. Appointments can be obtained. Furniture may be taken at a valuation. Premium, £250, of which part may be paid by instalments.

A 10. LONDON, S.W. Private Practice with Open Surgery. Receipts, £500. No horse or carriage necessary. House in an excellent situation, and in an improving neighbourhood. Rent, £50. Easy terms.

A 17. LONDON SUBURBS, S.W. Good class Fee Practice. Partnership offered. Receipts, £1,400 a year. Midwifery, £5 5s. A small Share may be taken at first with Succession to the whole in 3 years, if desired.

NOTICE.—Dr. LANGLEY'S QUARTERLY LIST of SELECTED PRACTICES and PARTNERSHIPS for JANUARY is now ready. Post free on application.

IRISH POOR-LAW INTELLIGENCE.

WHISKY AT WAKES.

Mr. FERGUSON, Q.C., Chairman of the East Riding of county Cork, addressing the grand jury at Bandon quarter sessions, deplored the custom of drinking at wakes and funerals, and said the only serious case that came before them arose outof this practice. It occurred to him that this might to a great extent be remedied by the clergy. They would be quite justified in prohibiting the use of intoxicating drinks at those wakes. He knew of a clergyman who refused inariably to go into a house where intoxicating drink was at a wake, and the result was that no such disorderly scenes ever occurred in his parish.

FINTONA DISPENSARY DISTRICT.

ELECTION OF MEDICAL OFFICER.

A SPECIAL meeting of the Committee of Fintona Dispensary has been held in the committee rooms to elect a medical officer in the room of Dr. A. H. Robinson, resigned. Two candidates were to the poll—Dr. Thomas Duncan, Fintona, and Dr. Clarke, Tempo. There were 19 members of Committee present; 14 voted for Dr. Duncan and 5 for Dr. Clarke; the former was declared duly elected by a majority of nine votes.

BOYLE UNION.

FEES FOR PROSECUTING VACCINATION DEFAULTERS.

(From the *Roscommon Herald.*)

A CLAIM was made some short time since by Dr. Kisby, *Medical Officer* of the Ballyfarnon dispensary district, for *one guinea*, claimed by him for assisting in a prosecution against defaulters under the Compulsory Vaccination Act. This claim was supported by a certificate signed by a magistrate presiding at Ballyfarnon petty sessions. The demand made by Dr. Kisby came before a meeting of the Board of Guardians and was refused on the ground of no expense having been incurred.

A communication was read from the Irish Medical Association threatening to take legal proceedings against the Boyle Board of Guardians to recover the sum claimed by Dr. Kisby.

Mr. Mulhall—If a man had to travel five or six miles to attend a prosecution he ought to be paid, but he merely walked across the street from his own house.

Major Ferrall did not think the letter received from the Irish Medical Association had anything to do with the Board

The Chairman suggested that the letter then before the Board should be sent to Mr. Harkan for his opinion on the matter.

Major Ferrall—You might do that; but I think the letter of the Irish Medical Association ought not to be replied to.

Mr. Stuart—If a doctor had to pay car hire, or expenses of a witness, it would be well to pay him.

Chairman—But I think the Irish Medical Association did not write that letter without having legal opinion.

Mr. Stuart was of opinion that the letter from the Irish Medical Association ought to be answered, stating that no expenses had been incurred by Dr. Kisby in the case to which they referred.

Chairman—If they are to be replied to, I would be for first having the opinion of our solicitor.

The Board agreed to the Chairman's proposition.

DROMORE WEST UNION.

THE Clerk read the following letter, forwarded by the Local Government Board for the guardians' observations upon it, to consider which this meeting was specially summoned:—

"Dromore West, Dec. 5th, 1875.

"GENTLEMEN,—I beg to inform your Board that a man named James Loftus was admitted to the Dromore West Union Workhouse on 19th Nov. ult. He died on the morning of the 29th, and he died without having administered to him the last rites of the Catholic Church to which he belonged. On inquiry I found that the medical officer of the workhouse came on the day previous to the man's death at 3 o'clock p.m., and left at a quarter to four. I believe by the rules of your Board that he is obliged to attend not later than 12 o'clock noon. I have it on the authority of some of the inmates of the ward in which this death took place, that on that day the doctor merely stood a little inside the door, and never examined either Loftus or any other inmate, although there are two others confined to bed. Loftus must have been then in a most dangerous state, as he was suffering from some severe disease, and was very feeble when admitted. The distance from the door to where the sufferer lay uncared for, is eleven or twelve yards, and surely the doctor, be he ever so clever, could not have done him much service at such a space. And all night long in that dreary ward the poor creature cried, 'for Heaven's sake will any one get me a drink—I am burning with thirst!' And neither the idiot boy who is chief attendant there, nor any other person replied to that touching, pitiful appeal. Later on, the master, with Christian kindness, called the hospital nurse, and told her, for God's sake, bring the man a glass of wine to keep him alive until the doctor arrived, and he added, 'the wine we have to give is so weak that it cannot do any harm. The wine was brought. The man drank it, and he shortly after lay back dead about twelve o'clock! I now inform your board that the medical officer of the workhouse of the dates above stated, and whom the guardians, or at least a section of them, by their resolutions in your keeping, endeavoured to defend, is the same complained of in my letter of October 16th. He was appointed *locum tenens* to the dispensary and workhouse here on Nov. 16 ult. Gentlemen, he was re-appointed to this situation of medical officer to the workhouse by the vote of guardians who ought to be guardians of the poor. He was appointed on November 26th, ult. How has he dischrrged his trust? Hours of attendance:—Nov. 28th, from 3 p.m. to a quarter to four (this was the day preceding the death of the man Loftus before referred to); November 29th, 12¼ p.m. (this was the day of the poor man's death); Nov. 30, date of

that while additional provision is being gradually made for the insane community, the ratio of lunacy to the general population cannot be regarded as on the increase, bearing in view that the invariable results of enlarged asylum accommodation is to bring under treatment chronic cases of diseases which before were unheeded, or not enumerated, and that latterly individuals, natives of Ireland, who after emigrating to America or settling in Scotland, on becoming insane are not unfrequently sent back to this country—furthermore it should be remembered that within the category of mental disorders a disposition is new prevalent to include various manifestations of the mind which previously were not regarded as typical of genuine lunacy. Extravagance of conduct when carried to excess, the squandering of means without any ostensi- benefit, confirmed habits of drunkenness and dissipation, as well as continued discontent and waywardness of feeling, particularly if associated with a disregard to social duties, are looked upon in a new light, and attributed to unsoundness of mind. It is no doubt most difficult in many instances to draw a line of distinction between responsibility of action and lunacy; one fact, however, would appear certain, namely, that in 1875 people are considered insane, who thirty years ago would be held in a different estimation. Hence, perhaps, in addition to actual lunacy as evinced by the test of delusions arises the reputed extension of mental disease.

From the statistical tables before us we find that the registered insane had increased during the year 1874 by 257 patients, and that those at large had declined by 177. Contrasted with the state of lunacy in England as officially recorded, a marked difference is observable, for within the period under consideration there has been a very distinct progression in the development of lunacy in the sister country, so far as can be judged of by the actual numbers under treatment and totally exclusive of those who are at large.

This disparity, however, may in no small degree be accounted for by the organised facilities we possess of obtaining information through the police and constabulary in Ireland, who for a series of years have annually afforded the Inspectors particulars as to the reputed insane not under governmental supervision, including within the general denomination not only actual lunatics but epileptics, idiots, and imbeciles. This information cannot however be accepted as strictly accurate in every case, for practical purposes we place confidence in it as being closely approximate, and the more so as succeeding returns fairly support in detail the correctness of preceding ones, a fact previously we had occasion to remark. The total of all classes on the 1st January, 1874, was 6,981, and on the same date in 1875, 6,804.

The registered insane or those in public and private institution amounted at the opening of the present year to 11,583. The population of Ireland being 5,456,000, the ratio of such lunatics per 1000 may be set down at 2·14, but as obtains in other countries, particularly in Scotland, on examination in detail their proportion would not be found uniform throughout different provinces or counties.

(To be continued.)

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER VI. (*continued from p. 489 of last Vol.*)

THE PATHOLOGY OF EPILEPSIES.

The next question is, *How do changes beginning in non-nervous elements damage nervous tissue so as to cause "discharging lesion"?* Obviously in many cases we can only speculate on this matter, for of many cases it is clearly but an hypothesis that the change does begin in non-nervous tissues. I would remark to those who think that in some cases, as in genuine epilepsy of authorities, the pathological process begins in the nervous elements, that that is an hypothesis too. But referring to that, I have said (Dec. 15, p. 488) I would repeat that, of nervous diseases *of which the pathology is known*, there are very few, and possibly *none* in which the pathological change *begins* in the nervous elements of the nervous organ affected.

The pathological processes which lead to the one condition of grey matter instability are no doubt numerous. I can only speak with any degree of confidence of two processes which I believe to start in the non-nervous elements of nervous organs.

1. Occlusion of vessels (embolism and thrombosis).
2. The "irritation" of coarse disease.

1. *Occlusion of vessels.*—The reader will bear in mind that we are seeking the causes of instability, not the cause of some clinical entity. Thus the remarks apply to the production of changes of instability in general. I will, then, speak first of an hypothesis as to the mode of production of instability in chorea.

The following is, with a few verbal alterations, from a paper I contributed to the *Medical Times and Gazette*, March 6, 1869. It applies equally well, I think, to instability in some cases of epilepsy. When I first put forward my speculation on the pathology of chorea I did not know that blocking of arteries most often caused hyperæmia. I used to say it caused anæmia. In the paper from which the following is a quotation I made the necessary correction.

"If arteries be plugged, it seems certain that the nutrition of parts they supply will be *imperfect;* still, it does not follow that it will be *decreased.* For, according to certain physiological experiments, it seems that plugging of a small artery does *not* always cause *anæmia* of the capillary region to which the vessel should deliver arterial blood. On the contrary, it may cause *congestion,* and may even lead to extravasation. I must, for the facts and arguments of this question, refer the reader to MM. Prévost and Cotard's work, "Etudes physiologiques et pathologiques sur le Ramollissement cérébral" (Paris, 1866), and especially to a section (p. 38), "De la congestion qui accompagne infarctus." I will only quote the last of the three conclusions from their experiments (italicising some words):—"Consécutivement aux *oblitérations artériales* il se produit habituellement de *l'hyperémie* et de la tuméfaction," &c. Dr. Ivan Poumeau has also published very interesting statements on the effects of plugging of vessels.—"Du Rôle de l'Inflammation dans le Ramollissement cérébral," 1866.

. . . . . .

"As it seems to me, the local increase in quantity of blood . . . has an important bearing on the production of chorea *and other symptoms implying increased expenditure of force.* If it be venous we may suppose that although nutrition may be carried on faster, it will lead to *more imperfect* and more easily decomposable nervous matter, or if we suppose the nerve force is supplied from the blood to the nervous structures in the same way as recent investigators believe force is supplied to the muscles, the increase in the quantity of blood is still significant when associated with increased expenditure of force. I suppose we may fairly say that the general character of blood, which is stagnant or slowly changed, will be venous rather than arterial.

Since this was written Cohnheim's researches have ap-

peared. He thinks as Virchow does, that the hyperæmia and extravasation in the infarction result from venous reflux.

This speculation seems to me to accord with the speculation given Nov. 3 as to the alteration in Composition of nervous matter in "discharging lesions." From such a morbid stagnation of blood as embolism causes we should expect a greater quantity of nutrition, but one of a more general character, of worse quality. I suppose a tissue of more nitrogenous and less phosphorised composition. And it harmonises too with the dietetic treatment of epilepsy adopted by James Jackson, West, Trousseau, and Ireland. (*a*)

Let me now speak on conditions for embolism in association with convulsion. Some clinical facts are, I think, indirectly, evidence in favour of the production of local instability by occlusion of vessels.

It is not very uncommon to find when a patient has recovered or is recovering from hemiplegia, the result of embolism of the middle cerebral artery, or of some branch of this vessel, that he is attacked by convulsion beginning in some part of the paralysed region, almost always, I believe, the face or the hand. I have not, however, yet made a post-mortem examination on a patient whom I knew to have had fits *of this kind* after supposed embolism. It will be safer, then, to say that such seizures occur in patients who have recovered partially, or seemingly entirely, from hemiplegia occurring with heart disease, or with the parturient state. And as I have made no port-mortem examination in any such case I will not relate any cases in illustration. I have recorded several cases of the kind in a paper on "Loss of Speech," in the first volume of the "London Hospital Reports," 1864. (*b*)

Dr. John W. Ogle and Dr. Murchison have drawn attention to the fact that aneurisms of the larger cerebral vessels have been found in patients who have been subject to "epilepsy," that is, to chronic convulsive seizures before the fatal one due to rupture of the aneurism. Mr. Callender ("St. Barth Hosp. Rep.," 1867, vol. iii., p. 426) has made the very important observation that "the epileptic attacks belong to aneurism of the middle cerebral artery." I have, in vol. vii. of the "Lond. Hosp. Reports" above referred to, spoken of the significance of the fact of aneurism of the middle cerebral artery being attended by fits. But I know of no case on record *in which the particular kind of fit associated with aneurism of that vessel has been described.* I surmise that in these cases the convulsion begins on one side, but I have, I repeat, no facts on the matter.

I do not think as I then did (1864) that in cases of embolism the *persistent* condition of nerve tissue on which the fits depend results from *diminished* supply of blood to healthy nerve tissue in this vascular region. Plugging of small branches of the middle cerebral artery would lead to congestion, and thus to over-nutrition, and consequent instability of the convolutions (and possibly of the grey matter of the corpus striatum).

Venous Thrombosis.—There are cases of disease of the ear (attended by discharge) with which epileptic or epileptiform convulsions occur. I believe the accepted explanation is that these seizures are due to reflex action, the results of irritation starting from the ear. My speculation is that the local instability on which they depend is the result of local hyperæmia from infarction of cerebral veins; it is, I suppose, a result of a minor degree of the same process as that which sometimes leads to cerebral abscess. I do not enter into this matter here. I may refer to remarks on the subject—*Brit. Med. Jour.*, June 26, 1869, p. 591, and to the *Med. Times and Gaz.*, Jan. 6, 1872; in the latter there is adduced evidence that venous thrombosis causes instability and indirect evidence that disease of the ear may be the origin of such thrombosis.

Coarse Disease.—By coarse disease I mean such disease as tumour (including syphilitic growths and masses of tubercle), cysts, abscesses, &c. All these are "foreign bodies."

This subject is far too extensive for full treatment here. I must, then, speak categorically. Any one of these foreign bodies may be latent; for as we have seen, much of the brain may be destroyed when there are no symptoms of any kind. They often do not produce symptoms of importance by their direct action, *i.e.*, because they destroy so much either by involving a part in their growth or by squeezing other parts. There is another way in which they can act. They are sources of irritation, (*a*) and thus, I suppose, cause a local encephalitis. Speaking otherwise I would say that they produce instability of grey matter about them by irritation. The chief symptoms of the instability they produce are headache, optic neuritis, vomiting, and convulsion.

Eccentric Irritations.—There is yet another way in which it is believed by most physicians that local instability may be developed—viz, by eccentric irritations. The case of tetanus is very striking.

We have to distinguish betwixt irritations discharging nerve tissue already unstable, and irritations causing that instability. It may be however that we have here only two degrees of one thing. What Reynolds says strikes me as most to the point. He writes:—"The general mode in which an eccentric irritation passes over into convulsion is the same in each instance—viz., by inducing the peculiar organic condition upon which the paroxysm depends. An impression made upon an afferent nerve determines, not only in it, but in the centre to which it is attached, an interstitial change; and this latter is the cause or essential condition of a motor impulse, which is transmitted along a motor nerve to the contractile fibres of the muscles or the vessels. In such conversion of impression into motion, we have the simplest idea of a 'reflex' action."—Reynolds' "Epilepsy," page 18.

This subject always makes me recall cases mentioned by Sir James Paget in a lecture he delivered many years ago—neuralgia set up by injury persisting when the nerve to the injured part was divided. It seemed as if the local injury to the nerve had led to permanent changes of instability in some connected part of the sensory centres, for the patient continued to feel pain in the injured part when it was quite anæsthetic from surgical division of the nerve trunk supplying it. (*b*)

Eccentric irritations will have to be considered more carefully later on. It is a matter of great importance, as everyone acquainted with Brown-Séquard's researches knows.

Appendix 1.

Although I speak in the text, as is the custom, of the body as if it were made up of tissues, I think the expression is not a correct one. I no more believe it to be a scientifically adequate expression to say that the body is made up of tissues than to say that a language is made up of words. Language is made up of propositions in which words are arranged in a particular order of inter-dependence; I believe that an organ is made of tissues arranged in a

(*a*) In the just issued fifth volume of Crichton Browne's "West Riding Asylum Reports," there appears a most valuable paper by Dr. Merson on "The Influence of Diet in Epilepsy." I shall refer to and quote from that article in an Appendix to this Chapter.

(*b*) I think it very likely that in some cases of convulsion after embolism we should find post-mortem aneurism of a branch of the middle cerebral artery. The autopsies I have had in cases of death by rupture of aneurisms of large cerebral vessels tend to confirm the view Dr. John W. Ogle has put forward as to the causation of aneurism by embolism. For facts in support of this view see Dr. Church's admirable paper, "Contributions to Cerebral Pathology," "St. Barth. Hosp. Reports," 1869.

(*a*) Dr. Burdon Sanderson, in his first "Lectures on Inflammation" (see Abstract, *Lancet*, January 8, 1876), writes:—"—" such words as 'irritation' must be got rid of—words which, in their original meaning, assume a property of irritability, and we must substitute for it the phrase 'injury of tissue.'"

(*b*) If so, it is but a caricature of the process by which such changes are established in nervous centres by outward objects as enable us to see the objects ideally during subsequent excitations limited to these altered centres.

particular order of inter-dependence. Using the chemical terms composition and constitution, we may say that an organ is Composed of tissues, but is Constituted by particular arrangements of tissues. Thus, a piece of brain is composed of connective tissue, arteries, capillaries, and veins, as well as of nerve cells and fibres. The functional unit (the nervous organ in miniature) is, however, constituted by the particular relation which its components have. The nervous is the leading tissue, subordinate to it is a circulatory system (artery, capillaries, and veins), and probably there is a nervous system by which, according to requirements of the leading element, the arterial tonus is increased slightly, or the artery is strongly contracted. Perhaps there is inhibitory action. Lionel Beale writes of the frog :—

"If a small artery be brought into focus and the tip of one of the toes be very lightly touched, the artery is seen to contract immediately, and somewhat irregularly, in different parts of its course. Sometimes a few blood corpuscles are firmly compressed, and for several seconds the vessel remains so strongly contracted that not a corpuscle passes along it. By performing this instructive experiment the observer may realise the effects of the wonderful contractile power of the coats of the smaller arteries, and demonstrate conclusively that the afferent nerve fibres distributed to the skin of the foot generally, influence the nerve centres from which the nerves ramifying amongst the muscular fibres of the arterial coats take their rise. This is a beautiful instance of reflex nervous action affecting the vessels." ("How to Work with the Microscope," Fourth Edition, p. 135. See also Beale's Croonian Lecture, 1865.)

Beale writes also (*op. cit.*) :—"In many instances ganglia are seen in connection with the nerves ramifying amongst the muscular fibre-cells encircling the vessels. I have seen such upon the vessels of all the viscera and those of the palate of the frog : they are to be detected on the iliac arteries in considerable number. The results of Mr. Lister's experiments render it probable that ganglia exist in connection with the arteries of the limbs."

My hypothesis is that in every nervous action there is a physical change not only in the nerve cells of the nervous Unit, but in its arterial system. In some cases where the functional exercise of the leading element is excessive, there results, we may suppose, loss of "tonus" in the over-tasked arterial system. It becomes exhausted : an illustration is that from over-use of hypermetropic eyes there ensues great redness, and even some swelling of the *optic discs.*

I think that on this principle we may account for the *origination* of some degenerations—atrophy of optic nerve, chronic Bright's disease.

I submit that degeneration is not the first thing. It is plainly not so in degenerations of arteries. There is here a prior active stage called endarteritis.

Before degeneration sets in there is, I submit, as an indirect consequence of *over-use* of the leading elements (nerve cells, gland cells, &c.), a stage of arterial relaxation permitting increased quantity of blood and yet less change of blood. This is a circumstance unfavourable for the proper nutrition of the tissues of leading function (nervous, gland cells, &c.), and comparatively favourable for the proper nutrition of the tissues of subordinate function (connective tissue). The leading elements will be over-fed and yet worse fed, and thus will easily degenerate (slowly "decompose"). We see how there results degeneration of nerve elements and increase of connective tissue. In the optic atrophy of so-called tobacco amaurosis there is increased redness of the discs before atrophy sets in. The pains of locomotor ataxy are, I think, the signs of active changes, which lead to further degeneration. Pathological changes causing pains cannot be merely degenerative.

Of course, widespread arterial relaxation is produced in other ways, by the ingestion of alcohol for example. Local capillary repletion is produced by embolism or thrombosis of arteries.

This hypothesis as to "functional units" brings nearly into one the two hypotheses (see Chapter 1, Oct. 21, 1874) that the hereditariness of disease is (1) a tendency to disease of particular tissues, and (2) of an inheritance of imperfectly developed organs. An ill-developed organ is, in the case of an organ like the kidney, one which has few "functional units," in the case of the brain, where the units differ, one in which the most special units are few. The inheritance of a tendency to phthisis is, I think, not an inheritance of a tendency to any kind of tissue change, but an inheritance of small lungs ; the smallness of the lungs being inferrible from the size and the expiratory form of the chest. The small organs are organs easily overworked, there is less reserve.

Appendix 2.

Dr. Merson writes (*op. cit.*) :—"Another way in which the nutrition of the brain may be influenced through the food is by the effect of the latter on the circulation, and the general nutritive activity of the system. Dr. Parkes has proved that the power of the heart's action is capable of being diminished by a reduction of the nitrogenous principles of the food, especially if the voluntary muscles are kept in active exercise. A man was fed for five days on a diet of non-nitrogenous matter, consisting of fat and starch alone. It was found that the voluntary muscles, excited by the will, could act with as much force as ever, although starved of nitrogenous matter ; but it was not so with the involuntary muscles. The heart soon began to suffer in nutrition, and its force, as shown by the sphygmograph, was reduced nearly one half. 'I draw the conclusion from this experiment,' says Dr. Parkes, 'that if the nitrogen is cut off and the voluntary muscles are kept in their usual action, they do not fail ; but that the power of the heart may be thus reduced if it be desired to do so. In other words, the food the heart requires is attracted from it by more potent actions. Here, then, we possess a power of affecting the action of the heart if it be needed. *The same remarks will, of course, apply to the muscular tissue throughout the circulatory system.*"

These statements, especially the concluding sentence which I have italicised, are very important. I had overlooked the facts Dr. Merson mentions.

Dr. Merson concludes, as regards his experiments :—"On a review of the whole evidence furnished by these observations, I think, after making due allowance for all circumstances likely to tell in the opposite direction, that these are fair grounds for the conclusion that a farinaceous diet is likely to be more useful in the treatment of epilepsy than a nitrogenous ; but in order to get satisfactory results, observations would have to be extended over a longer period than was at my disposal in the present instance. I hope, however, to continue these observations, and at some future time may record the results of my further experience."—Merson, *op. cit.*

Dr. Merson does not, however, find that the administration of phosphorus is of value, as according to my speculations it should be. I should, however, like much to hear of observations by Dr. Merson on the use of arsenic instead of phosphorus. It is one of the congeners of phosphorus. I have suggested (see foot-note, p. 356) that the therapeutical value of the iodide of potassium is due to its replacing its congener, the commoner, and as I suppose, less potent haloid, the chloride. I believe there is a Substitution Nutrition. Similarly it may be that arsenic will replace the phosphorus, and lead to nervous tissue of more stable constitutions.

The central nervous system and the superficial layer of the skin have one embryological origin. It is well known that arsenic is a valuable remedy in certain skin diseases. Dr. Broadbent, who believes that substances which have a chemical relationship may have allied therapeutical powers, has, in illustration of his doctrine, suggested the use of phosphorus in certain skin diseases.

FOR AND AGAINST ANIMAL VACCINATION. (a)

By CHARLES R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S. Eng.,

Senior Physician to the Metropolitan Free Hospital; Physician to the North London Consumption Hospital; and Consulting Physician to the Farringdon General Dispensary.

Continued.

The animals which enter the cow-houses of the Institute in good health leave it in the same; the vaccine process does not in any way affect them; and if some of the youngest subjects have sometimes appeared to suffer during their stay, it is because they entered it in bad condition. The use of older animals does not prevent such accidents. The whole secret lies in not admitting any animal for vaccination unless it be in good health. It has been supposed that it might be possible to avoid such illusory objections by only employing heifers of eighteen months old, and drawing from them more certain and better elaborated products than those furnished by younger animals. Experience has not confirmed such perfectly theoretical views: for, at Milan, where the committee of animal vaccine employs only animals of this age—not from preference, but because there are no young calves sold in the market, since the Milanese exclude such young calves from the table—the products obtained are not in any way superior to those of the Institutes of Naples, Venice, or Bologna, nor, above all, to those of the Institute of Verona, which has a special reputation in Italy, and where vaccinal lymph is, as it is at Brussels, exclusively kept up on young calves of two or three months old.

Dr. Warlomont says that it is animals of this age which have appeared to him the most suited to the culture of animal vaccine; besides that they have always yielded lymph in sufficient abundance, this lymph has succeeded in the hands of all who have understood how to use it, and in a proportion which leaves nothing to be desired. He adds that calves of this age are, of course, more easily managed and handled than when they are older.

A certain predilection, legitimate or not, we know, is attached to the lymph which comes from cows at the period of lactation. Such vaccinifers, evidently, could not be suitable for a culture designed to furnish regularly large quantities of cow-pox. This would be ruinous and impossible. Nevertheless, in order to afford, as far as possible, satisfaction to a respectable desire, a middle course has been hit upon, suggested by the practice carried on in Bavaria. It seems that in Bavaria, in order to prepare the vaccine d'Etat, it is the custom annually to pass the lymph of an infant, in view of regenerating it, through a milch cow. The vaccine lymph thus prepared is inoculated on children. and the product of this transmission is distributed officially. Dr. Warlomont remarks on this Bavarian practice, that the passing of the cow-pox through the arm of an infant is probably due to it having been found that cow-pox is not transmissible by means of tubes, and that ivory points have not yet made their way into Bavaria. "It is the Bavarian method," he adds, "which we apply, by periodically passing the vaccine of the calves through a milch cow. The vaccine d'Etat is thus always derived from spontaneous cow-pox, kept up on the bovine species and renewed in the eyes of the most exacting by periodical transmission through the organism of those animals which are indicated by popular opinion as being best fitted to restore vigorous and unimpeachable products."

Speaking of vaccino-syphilitic contagion, Dr. Warlomont said, in 1871: "I have never had any intention of discrediting human vaccine to the profit of animal vaccine. Six years ago facts about vaccinal syphilis, well or ill established, were pointed out and brought to our ears by every wind of Heaven. We were at our wits' end. Add to this the fact that we constantly met with children of four and five years old, vaccinated some years ago, and yet seized with fatal small-pox, or when revaccinated, yet have legitimate vaccine vesicles. The conculsion was drawn that the lymph was not only poisoned, but that it could no longer be depended upon as a preservative agent. What was the consequence? Some one came and said to the public—You who, under the pretext of adulteration, or exhaustation of the human virus, refuse to allow your children to be vaccinated, or to revaccinate yourselves, go to the heifer, this will no longer give you any pretext for indifference or defection. And, on hearing this, the whole world ran, trembling with fear, to the heifer."

On this point Dr. Marson (*Reynolds' System of Medicine*, 1866) mentions that four-fifths of the admissions to the London Small-pox Hospital are now for the disease in persons already vaccinated. He attributes this mainly to careless vaccination; but (p. 476) he adds, "It is a question that may be fairly and properly entertained, whether we ought not to resort more frequently than has hitherto been done to supplies of lymph from the cow." It must be remembered that from 1796 to 1825, there was no epidemic of small-pox in London: then came the epidemic of 1838; then that of 1840-41, then that of 1844-5, and 1848; then that of 1851, and of 1854-5-6, of 1859-60, of 1863-4-5; then that of 1871. Does this mean that the early vaccine period was the most preservative? Or does it mean that the process of vaccination has fallen into less careful and instructed hands than it was when the immortal discoverer of vaccination was alive?

Dr. Seaton contends (*Reynolds' System of Medicine*, 1866, p. 490) that, ordinarily, persons who have once been successfully vaccinated are permanently protected against small-pox. He maintains, too, that of 20,590 deaths from small-pox which occurred in England and Wales in the six years ending 1861, 5,010 were in children under one year of age (loc. cit., p. 489). Marson gives the aggregate mortality with good vaccine scars, from small-pox, uninfluenced by other diseases, at only 2.52 per cent.; the aggregate mortality with indifferent lymph, at 8.82 per cent.

Dr. Warlomont states that the importance of only using early lymph in animal vaccination is still more marked than it is in human vaccination. An experience extending over several thousands of vaccinations has left him in no doubt on this point. At first he only vaccinated with vaccine-vesicles of the seventh or eighth day and then often failed. Afterwards he advanced a day and found his success at once more constant. Again advancing the period of his vaccination, he tried the vesicles of the fifth, and even of the fourth day after inoculation. Then it was that no vaccination any longer failed to take, and he renounced the employment of vesicles of greater age than five days. So that he no longer keeps the calves more than four whole days in the cow-house of the Vaccinal Institute. It is within a period extending from the middle of the fourth day, and, in summer, from the commencement of the fourth day to the end of the fifth, that the heifer gives the best lymph. This is at that period quite limpid, and less coagulable than when it is more ancient; the vesicles, too, may be compressed by means of a forceps, which, of course, is impracticable in the case of infants.

Tubes.—The results furnished by animal vaccine in tubes are far from approaching those given by arm to arm vaccination. Mr. Seaton attributes this to the heat necessarily employed in the case of human vaccine. In his "Handbook of Vaccination" of 1868, p. 150, he shows that, whilst arm to arm vaccination has failed in Dr. Husband's hands only once in some 150 cases, that by means of tubes has given 10 per cent. of failures.

Ivory Points.—Both Seaton and Marson declare (loc. cit., p. 150) that when human lymph is used the balance in favour of ivory points over that of tubes as a means of preserving lymph is very great. Hubert, of Louvain, declares, too, on the head of another detail of animal vaccination, that of scarification, instead of puncture, that he has used only scarification for some thirty years, and has hardly witnessed one failure in 1000 persons

(a) Read at the Medical Society of London on the 15th November, 1875. Dr. Routh, President, in the chair.

in arm to arm vaccination, when the subject was a virgin one. Animal vaccine cannot be preserved at all in tubes, since the specific part contained in the more solid portion of the lymph separates from the more fluid. So that, in general, out of twenty tubes of animal lymph, however carefully filled, there are nineteen which must be rejected, even in twenty-four hours.

At first Dr. Warlomont sent out much animal vaccine in tubes, but the failures were so frequent that the process seemed likely to be abandoned, except in the case of heifer to arm vaccination. Fortunately, just in proportion as animal vaccine is ill-suited for preservation in tubes, it is well suited by its physical properties for the English plan of preserving on ivory points. It was to an English medical practitioner, Dr. Blanc, that Dr. Warlomont confesses himself indebted for discovering that the use of ivory points is the best adapted for the storing up of animal vaccine. This gentleman, in 1869, after returning from Abyssinia, studied animal vaccination for some time in Brussels, and then attempted unsuccessfully to introduce the practice into London, where, however, it did not take. Animal vaccine lymph is very plastic, and thus easily adheres to the point, and does not penetrate too deeply into its substance. On the other hand, the use of a compressing forceps makes the lymph exude from early vesicles, possessed of great virulence, and thus the points can be coated with a very active lymph. To do this well, the points are charged with two coatings at least, by plunging them in the drops of lymph expressed from well-chosen vesicles, and dried in the air, or by suitable heat. Vaccine thus prepared brave the action of the external air for a period, which experience has not yet definitely settled, but which varies from fifteen days up to several months.

To prove this latter fact Dr. Warlomont gives a letter from Professor Neffe, of Ghent, who, on August 5th, 1871, received three points of animal vaccine, and made use of one of them. Forty-nine days afterwards he successfully vaccinated another child with the other points. Dr. Blanc also, in a letter dated Bombay, April 27th, 1871, mentions that in January, 1871, six points were sent him from Brussels. All these six points succeeded both on calves and on children inoculated by them. Some of the said points were forty-five days before they were used.

As to the success of vaccination by means of the ivory points of animal lymph, Dr. Warlomont gives us very *full evidence that* it is extremely great. Thus Professor *Neffe, of Ghent*, in a letter dated June 7, 1871, mentions *11 vaccinations* made with them, with 11 successes, and 26 re-vaccinations on persons vaccinated in the year of birth, with 18 successes. Dr. Ansiaux, Professor at Liége, writing in March, 1871, says: "When points were substituted for the tubes, and the operation performed by means of little incisions, I recommenced my operations with animal vaccine. Then it was that no vaccination failed any longer, whilst revaccination gave 61 successes in 100 cases. Dr. Alexandre, of Sivry, writing in June, 1871, mentions that he moistens the point in water, and leaves it to soften for five whole minutes, then, rubbing the lymph on a piece of glass so as to obtain a milky drop, until, looking at it through the glass, it is all homogeneous and without any particles, or syrupy in consistence, he rubs it in."

Dr. Raikem, of Liége, writing in June, 1871, says:—"I find in animal vaccine the three following qualities: 1, a great guarantee of origin; 2, an almost certainty of success; 3, the sole method placed at my disposition for vaccinating with." This gentleman mentions that he had vaccinated with vaccine points 19 times, with 18 successes, and that he had made 132 revaccinations, with 67 successes.

Dr. Gallez, of Chatelet, writing in June, 1871, says:—"I have practised nearly 300 vaccinations and revaccinations, all, or almost all, directly by vaccine points, from the Institut, *i.e.*, without passing through a vaccinifer. The vaccinations have all succeeded, the revaccinations in two-thirds of the cases."

Dr. Moreau, of Tournai, writing in June, 1871, says he had never failed when he had vaccinated with ivory points furnished by the Institut. In the same month of 1871 Dr. Coppin, of Mortanweltz, says:—"From March 11th of this year small-pox commenced here, and lasted up till June 15th, during which time I have practised, with the points furnished by the Institute, 102 vaccinations on children from a few months old up to eight years. All have succeeded except two, who have resisted all methods hitherto tried."

(*To be continued.*)

ON A CASE OF TRANSPLANTATION OF THE CONJUNCTIVA OF THE RABBIT TO THE HUMAN EYE. (*a*)

By H. R. Swanzy, F.R.C.S.I.,
Ophthalmic and Aural Surgeon to the Adelaide Hospital and National Eye and Ear Infirmary, Dublin.

Early in last June a shopkeeper's wife from a provincial town came to me, complaining that she could no longer wear an artificial glass eye in her left orbit, owing to the cavity having become too small. This diminution in size of the orbit was owing to the formation of a band of fibrous tissue extending from the inner surface of the upper lid to the inner surface of the lower, at the outer canthus. It was probable that this band had had its origin in the irritation caused by an eye which had been worn too long, and had lost its enamel. I proposed to remove this impediment, and to this the patient readily agreed. I did not of course anticipate any difficulty in the excision of the band, but I thought it quite possible that there might be some difficulty in keeping the wounded surfaces of the two lids from uniting and producing even a worse condition than before; or that, if this did not occur, contraction of the cicatrices would soon leave the patient no better off. For these reasons I determined to attempt a transplantation of a portion of the conjunctiva of the rabbit to the cut surfaces.

Having procured a large black and white rabbit, I placed my patient on a couch in one room, and gave her an anæsthetic, while Dr. Fitzgerald chloroformed the rabbit for me in the next room. I had a small vessel of hot water ready, across the mouth of which I laid a microscopic glass slide. As soon as the animal was under the influence of the chloroform, I dissected off as large a piece of the bulbous conjunctiva as I could from each eye. I spread out these pieces as soon as removed on the object glass in the steam of the water, carefully noting whether the epithelial surface lay above or below. I then proceeded to my patient, and with a scissors excised the band of tissue close to its insertion into each lid. Its surface of attachment to the upper lid was much larger than in the lower lid, and consequently the cut surface here was also greater. Dr. Fitzgerald then everted the upper lid, and I took one of the pieces of rabbit's conjunctiva in two pair of forceps and spread it smoothly over the cut surface, taking care that the epithelial surface of the flap should be outside. Then, with some very fine needles and silken sutures I secured the graft in its place. I applied in all seven sutures, the size of the flap being about half an inch square. It covered the whole of the wounded surface of the upper lid. A bit of lint with simple dressing was then placed over the graft, the cavity of the orbit filled up with charpie, and a firm bandage was applied over the lids.

On the first day after the operation there was no apparent change in the graft; it was of a uniform grey colour On the second day, a small portion at the nasal side seemed to be assuming a pink hue. On the third day the pink hue was more decided, and extended over a larger part of the graft. Three sutures came away on this

(*a*) Communicated to the Surgical Society of Ireland on the 7th of January, 1876. The discussion will be found at page 72.

day. On the fourth day two more sutures came away, and on this and the fifth and sixth days the pink hue continued to extend over the graft, until it became difficult to distinguish it from any other part of the patient's conjunctiva. Examination with the point of a probe showed that not only the pink part, but also a portion at the outer margin which still remained grey, was firmly adherent to the parts beneath. On the tenth day the patient was allowed to return home, the remaining two sutures having been removed. The whole graft had become pink, except a small portion at the outer edge. It was hardly possible to distinguish the graft, except by aid of a strong convex glass, through which it might be discerned like a thin coating of mucous secretion over the place where it had been applied. I exhibited the patient at a meeting of the Biological Club. I have seen her only once since. She went home; but her husband, who was lately in town, told me that she wears her artificial eye now with great comfort.

I may mention that the rabbit seemed to miss his conjunctivæ very little. As soon as he recovered from the chloroform he began to eat and enjoy himself apparently as before, and as long as he continued under observation —it was some days—no evil effect resulted to his eyes.

Dr. Wolfe, of Glasgow, it was who, not long ago, first proposed to transplant the conjunctiva of the rabbit to the human eye. Since then the proceeding has been cultivated by Becker of Heidelburg, Wecker in Paris, and others on the Continent. It is chiefly employed to correct symblepharon, in which the lid becomes adherent to the globe, either from trauma, or as the result of granular ophthalmia, a condition which was incurable until this method and that of Mr. Teale were proposed. In two particulars this conjunctival grafting differs from the usual skin grafting. First, the transplanted portions are very much larger than in the case of dermic grafts; in fact, it is desirable to cover the whole wounded surface with the portion of conjunctiva. Secondly, the grafts are secured in their places by means of sutures. For a symblepharon of the lower lid, Wecker uses about 20 sutures. Wolfe and Becker use only four. In my case, as I mentioned, I used seven sutures; and I do not think one could err in putting in too many, while, if too few were employed, the graft would be liable to become displaced during the dressing.

Where circumstances admit of it, portions of conjunctiva from the opposite eye of the patient may be utilised as grafts, or the latter may be obtained from the orbit of a friend whose eye has been enucleated. Illing, of Vienna, in one case used grafts from the mucous membrane of the lip of the patient, and from the lip of a fellow-soldier. In another case, one of partial symblepharon, he successfully grafted a portion of mucous membrane from the vagina on to the conjunctival sac.

It occurred to me that transplantation of mucous membrane might be of use in some of the cases with which obstetric surgeons have to deal. Upon inquiring from Dr. Macan, he informs me that the method has been employed by Dr. Beigel, of Vienna. In a case of extensive ulceration of the vagina and cervix uteri, the grafts were taken from the mucous membrane of the healthy portion of the vagina. Dr. Beigel did not attempt to cover the entire granulating surface with the graft, but proceeded after the original method of Reverdin. The transplanted portions were kept in position by careful plugging of the vagina. In a second case of vaginal ulceration, Dr. Beigel transplanted particles of skin from the inner surface of the patient's arm. In both these cases, which had obstinately resisted all other modes of treatment, the transplantation brought about a complete recovery.

HER MAJESTY'S ironclad *Sultan*, arrived at Plymouth from Gibraltar, sent to hospital eight cases of scarlet fever. Two of the cases are serious. She left 20 of her crew in hospital at Gibraltar ill from the same disease.

A CASE OF SPINAL INJURY. (a)

By JOHN K. BARTON, M.D. Dub., F.R.C.S.I.,
Surgeon to the Adelaide Hospital, and Lecturer on Surgery in the Ledwich School, Dublin.

IRISH surgeons have happily not so much experience in the effects of railway accidents as our English brethren have, so that cases of spinal shock and injury such as Mr. Erichsen describes in his book on "Concussion of the Spine" are rare on this side the Channel. For this reason, and because the following case presents points of much practical importance to surgeons, I trust it may prove interesting to the Society, and that the questions suggested by it may be freely discussed. It belongs to a class of cases about which difference of opinion may exist even amongst the best informed surgeons, but when this difference of opinion finds publicity in a court of justice, and is magnified by the cross-questioning of lawyers, it becomes detrimental to the character of our profession. To prevent such exhibitions should be our object, and the best way to do so is by the free discussion of the difficulties that meet us in such cases as the following:—

Upon the 17th of May, 1874, I was sent for to see a lady who, I was informed, had been much hurt the evening before while walking with her sister upon the South Circular Road. I found the patient in bed. In her I recognised a young woman whom I had seen upon two or three occasions before for different ailments. She was tall, stout, florid, with reddish hair, and at the time of the accident in excellent health, the history of which was related to me as follows: A frightened dray-horse, over which the driver seemed to have but little control, came galloping down the road and came up on the pathway close to where the sisters were, and suddenly, without their being able to see how it occurred, the patient was knocked down, and immediately afterwards the horse was got off the pathway. The lady felt greatly hurt and shaken, but succeeded in getting into a cab, and reached her home, which was not very far off. She had been restless during the night, and felt pain and stiffness in the lower part of her back, where she said she had been struck, she believed, by the end of the shaft of the dray or cart. Upon examination I found a patch of ecchymosis about the size of the palm of my hand between the lumbar spinous processes and the posterior crest of the right ilium, partly over the spine, but extending considerably to the right side. The skin was not broken. Any motion of the lower part of the spine caused great pain. The pulse was somewhat quick, and her manner excited. The treatment adopted was rest in bed, and a sedative at night. The opinion given was that she was severely shaken, that there was no fracture, or apparently any serious injury of any part, but that the effects might be serious, that a few days would tell. The next day the patient's sister came in to say that she had slept badly, and was complaining much of pain in her back. I saw her again on the following morning, and found her dull and heavy, without much heat of skin, pulse not more than 84, complaining constantly of her back, both at the seat of injury and all the way up to the shoulders. Day by day this heaviness increased, so that in five or six days after the accident she could tell nothing about it. She lay in a semi-conscious state, capable of being roused, but when questioned about the accident she seemed to have forgotten it. At the same time the stomach began to be sick, and basinfuls of vomited matter, consisting of biscuits, liquid acid, and mixed with food, were shown to me daily; but I did not myself see her absolutely throwing off upon any occasion. About the same time the left side of the face became affected with a constant twitching of the muscles, by which the left corner of the mouth and the ala of the nose of the same side was kept alternately raised up and relaxed again. The sickness

(a) Communicated to the Surgical Society of Ireland on the 7th of January, 1876. The discussion will be found at page 71.

of stomach continued, while day by day the patient became less conscious of what was passing around her. She knew me when I went in; would hold out her hand and call me by my name, but soon relapsed into her customary condition of listless drowsiness. Always, when questioned as to her feelings, she gave the same answer, "*Pain in the back*," extending up to her neck and into her head, but chiefly in the back. Rubbing her back seemed to relieve the pain. Pressure anywhere she seemed to suffer severely from, not specially at the seat of the injury. Dr. Hudson now saw the patient, and agreed with me that the symptoms pointed to inflammation of the cord. She was placed upon a mercurial treatment, by inunction, and small doses of calomel by the mouth. The sickness of stomach prevented the use of bromide of potassium, &c.

Mr. Butcher soon after this saw the case, and to show the progress of the disease I may mention that at the consultation with Dr. Hudson she answered when roused all questions put to her regarding her state; but to Mr. Butcher she answered nothing, remaining with her eyes closed, and when he had left she complained bitterly of him, said he had broken her piano, and other serious charges equally untrue.

For about a month after the accident, although lying in a partially helpless state, yet when the bowels required relief she could be induced to rise, and could stand or walk a few steps; but about this time I was informed that she was becoming quite unable to stand, and upon examination of the limbs I found the feet and legs as far as the knees perfectly anæsthetic. No tickling, pinching, or pricking produced any sign of feeling or reflex movement, until the skin immediately above the knee was reached, when the patient at once showed signs of feeling and annoyance. The limbs, when raised off the bed by my hand, fell again, but not like a completely paralysed limb, there being a stiffness and rigidity about the muscles, which contrasted with the lifeless flaccidity of a totally paralysed limb. In attempting to bend the knee this rigidity of the muscles became still more apparent, for I found that no force I could use with propriety could bend the knee-joints. The anæsthetic condition of the limbs spread slowly upwards from day to day. I carefully examined this sign, and found the boundary line which divided the sensitive from the insensible skin, steadily advancing up the thigh. I marked with ink upon the skin this line, which was abrupt, and clearly defined, and found an inch, or sometimes more, was gained in two days, until it came up to Poupart's ligament, and even advanced two or three inches over the iliac regions on each side. Below it finally extended over the entire gluteal region, and over the sacrum. The urine was never retained, although I understood that it was passed very slowly.

While the anæsthetic symptoms which I have just described were in progress, the patient was becoming from day to day more insensible to outward impressions. She no longer recognised me when I entered her room, but lay with her eyelids closed, perfectly indifferent to everything passing around her. When aroused by her sister and asked did she know me, she for a moment would wake so far as to say a word or two, but immediately relapsed again into the same state. Her eyes, I have said, were invariably kept closed, the eyelid of the left eye constantly twitching, as I have already described; but when her lids were held open she appeared not to see anything, and when roused and asked did she see, she said, "No, that the room was quite dark." The light which at first distressed her made no difference now, and she lay facing it as well as with her back to it.

The diagnosis which I formed of the cause of these phenomena, and in which I was supported by my friends who saw the case in consultation, was that a slow process of inflammation had been set up in the nerves by the accident, which had extended up the cord, involving or including in its action the sympathetic ganglia. The treatment adopted was such as this diagnosis would suggest—mercury, leeches, spinal ice-bag, and blisters to spine and head. Aconite was given at first, but as the sickness of stomach came on, all medicine by the mouth was useless. To check this sickness we all in turn prescribed everything we could think of without the slightest, even temporary, alleviation. The patient was nourished by beef-tea enemata twice a day, which the bowel never resented or rejected. A little champagne or brandy was often taken, and frequently retained on the stomach.

This case became the subject of legal proceedings. Mr. Porter and Mr. Wharton saw the patient on the part of the defendant, who was the owner of the cart which was stated to have injured her; and Professor McDowel and Mr. Butcher saw her in consultation with me.

The state of the patient at the time of the trial was as I have just described it—she lay with her eyes closed, insensible to almost all outward impressions; she heard and spoke, but was to all appearance quite blind; she could not stand, while her legs up to her hips were absolutely without sensation. She was frequently vomiting, and was nourished by enemata. Under these circumstances there was but little room for difference of opinion. The evidence given by Mr. Butcher and by myself was to the effect that we believed her present state resulted from the accident, that we attributed it to a concussion of the spinal cord, and when asked did we consider that she would recover, or might recover, from the state she then was in, our answer was that, while it seemed to us unlikely, yet that we thought it possible; and when asked whether, if she did recover, we thought she would be permanently injured, we said we could not say, but thought recovery possible. The jury awarded substantial damages, and exception was taken by the defendants; not, however, to the surgical aspect of the case, where, happily, there was no unseemly difference of opinion. The subsequent history of this case renders it still more interesting; but here I am not stating what I have seen myself, but reporting what has been reported to me by others. I left town immediately after the trial for an autumn tour on the Continent, and did not see the patient again upon my return. I was informed by her sister, who had nursed her during the time I was in attendance upon her, that she continued in much the same state for about three months, that then the sickness began to be less frequent, and food was retained on the stomach, but that there was no other sign of improvement until the following February—fully six months from the time I last saw her, that then she was removed to Bray, apparently unconscious of what was being done with her, that then she slowly began to improve, in the spring she was able to be removed to Bangor, in Wales, and that there a much more rapid improvement took place. She is now quite well. I saw her a short time since, and found her free from any sign of disease. She says she cannot read more than a very short time without her sight becoming misty and her head confused. She is able to walk miles without fatigue or any return of the symptoms. She looks quite well.

The points in this case which appear to me of special interest are:—

1st. Can a reasonable doubt be maintained as to the genuineness of the symptoms? In other words—May the whole thing have been got up for a purpose? What lends colour to such a supposition is the manifest object which existed, and the complete recovery afterwards. But, on the other hand, the idea of exaggeration at least being possible occurred to me from the very first, and I carefully watched the patient from day to day to satisfy myself on this point, with the conviction being forced on me that the symptoms were genuine: the variety, unusual character, and slow progressive character of the symptoms also declared their genuineness.

2ndly. If we admit the genuineness of the disease, the next point of interest is the diagnosis. Were the symptoms due to hysteria or to inflammation? Hysteria is so loose a term that, as used by some, any signs of nerve disease may be called hysterical. But, if we understand by the term hysteria those reflex pains and emotional

excitements which we connect with functional derangements, there was nothing in common between the symptoms in this case and such. In the first place, the pain was never of the acute, sudden kind, and described as "terrific," or "awful," nor did it change from place to place. And, again, the symptoms were *progressive*, which, as Mr. Erichsen points out, distinguishes them from hysteria, in which the symptoms are as bad the first day as they ever are. It appears from that we are compelled to adopt the diagnosis which we made. The affection of the eyes which has been specially described by Mr. Wharton Jones is attributed by him to the cervical ganglia of the sympathetic being implicated, and this, amongst other reasons, induces me to think that these nerves have been the seat of inflammatory action in this case.

The third point of practical interest is as to the evidence which the surgeon should give in such a case. We must be prepared to answer, in the first place, the question—Is the state in which the patient now is the result of the accident? and also—Do you think she will recover, and if so, when? The answer I gave to the first of these questions was a distinct affirmative. To the second I said her recovery seems improbable, but I think it perfectly possible. As I understand that it has been reported that I said it was impossible, I am anxious that it should be understood that what I did say was that I considered it perfectly possible.

The fourth point of interest in this case is its remarkable termination. Although I thought her recovery possible, I confess that I was quite unprepared for so complete a restoration, and no doubt the case assumes a new interest from its termination.

Clinical Records.

PUERPERAL CONVULSIONS—CASE FROM PRACTICE.

By William Nolan,
Medical Officer Castleisland Dispensary.

On the night of the 3rd instant, at 7 o'clock, I was called on to attend Mrs. R., living about a quarter of a mile outside the town. I was told she was seized with a sudden fit; I knew nothing of my patient until I saw her, as she only came to live here lately.

I found the woman in convulsions of the most desperate type ever experienced. Her husband, on my asking him about her, told me she was in the family way, and he thought she did not know the moment she would be confined.

This piece of information gave me some clue to the nature of the case I had to deal with. He also told me it was her first child she was carrying. Her age I understood to be twenty-three.

In my presence she had fit after fit, with scarce a minute's interval, and in the intervals between the paroxysms she was in the most profound state of coma, attended with a snore. I had no chloroform about me, not knowing the sort of fit I had to deal with until I saw her. I at once made up my mind to bleed her from the arm; accordingly I watched for a quiet moment to do so, when, with the assistance of her husband, who held the arm and forearm for me, I took away about 10 oz. of blood. She got repeated paroxysms whilst I was bleeding her, which facilitated in a great measure the flow of blood, as the forearm and hand used to be convulsively clenched on the arm. The venesection having a good deal quieted her, I left her for a time, after examining to know whether labour had set in; it had not. I then handed her over to a midwife, with directions to leech her temples should she get a recurrence of the fits. I heard from her at 10 o'clock, and was told she had one attack since I left, and that the nurse applied some leeches.

I was called at 2 o'clock a.m., and was told she was in labour, and that the convulsions were as severe as when I first saw her. I saw her immediately, and took some chloroform with me. I found her in a fearful way, the paroxysms so great that she had to be kept forcibly in bed, or she would throw herself on the floor.

I made an examination, and found the os dilated so as to admit the fingers of my hand freely. There were, however, no pains, but I found the walls of the uterus moist and thin, and clearly dilatable if called upon to do so. I asked the husband to get me the assistance of the other doctor living in the town. He readily assented. Dr. Harold soon came to my assistance. We applied chloroform to nostrils, and put her well under its influence. The attacks ceased for a time, but only to recur with increased violence. As she had no pains, I proposed to my colleague that it appeared to me a case in which we might take a lesson from Dr. Johnston, late Master of the Rotundo Hospital, and follow his practice of delivering with the forceps, especially as I could introduce the greater part of my hand within the walls of the uterus, the head being within reach. Dr. Harold kept the poor woman under the influence of chloroform, whilst with careful manipulation I locked the short forceps of the Dublin School, Churchill's, I believe. After about half-an-hour I extracted a living male child; the infant from its small size seemed to be premature. After the child was born we found there was a second child. Now for the first time labour pains commenced. I then ruptured the membranes, and as the head came within reach, I at once applied the forceps, with greater facility this time, as I could encircle the entire head with the hand. After a little time (the pains assisting) I succeeded in delivering a second male child, which was equally as small as the first. The placenta came away with a pain at once—a single one; but the convulsions recurred as bad as before delivery. We again had recourse to the chloroform, with little benefit, except to subdue for a time their violence. We left our patient at 6 o'clock in the morning. I was asked to see her again at 9. I did so. I found her still in the same horrid condition. There was deep coma, eyes fixed, dilated pupils, frothing at the mouth, teeth clenched, surface of the body getting cold, and unable to be got to swallow anything. I directed her head to be shaved, and that I would try the effect of a blister. Her husband objected. I did not press him, as I thought her case now hopeless. She died at 2 o'clock a.m. The infants lived for 24 hours. They were strong when I made my last visit.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Friday, January 14th, 1876.

Sir William Jenner, Bart., M.D., D.C.L., F.R.S., President, in the Chair.

MORBUS ERRONUM.

Dr. Greenhow introduced a patient, presenting such marked pigmentation of the skin that he had been sent to Middlesex Hospital as a case of Addison's disease. He was a pauper about 60 years of age, and had doubtless been long exposed to the influences of dirt and vermin. Most of the regions chiefly affected in Addison's disease were here very deeply pigmented; but some symptoms, such as vomiting and breathlessness, which might be attributed to constitutional disturbance, were accounted for by cardiac disease. Possibly some cases, erroneously described as Addison's disease, without suprarenal affection, were examples of this kind of pigmentation, which Dr. Greenhow proposed to style "morbus erronum." The pigmentation, however, was more mottled and less uniformly distributed than in Addison's disease. Moreover, the face and hands were least discoloured, and repeated applications of detergents diminished considerably the depth of tint.

CONGENITAL FATTY TUMOUR.

Mr. E. Venning related the particulars of this case.

C.E.G., a male child, aged 8½ months, was seen in July last. At that time, a tumour was found situated on the right buttock, rather to its inner side. It was first noticed by the mother at the birth of the child, and was then about the size of a pigeon's egg. Its surface was very red, and she remarked that it began to increase in size when the child was two months old. When seen in July last, it was of the size of a Tangierine orange, its surface was of a dark red colour, it was elastic to the touch, and became much more tense when the child cried. There was no impulse, and it had no connection with the rectum. It so much resembled a large nævoid growth that it was diagnosed as such. The growth was then divided into three portions by strong silken ligatures, and for a time they seemed to be contracting rapidly. In September, the case was again seen, when it was found that rapid growth had taken place, and the tumour was then as large as a moderate sized orange. Extirpation was decided on and performed. Very little hæmorrhage took place. The tumour was found to consist of fat, very like fœtal fat, and differing considerably from the usual appearance of a fatty tumour occurring in adults. Remarks were first made on the difficulty which was experienced on arriving at a correct diagnosis of the nature of the tumour, as it presented so many of the characteristics of a large nævus, and secondly upon the rarity of fatty tumour occurring in a congenital form. Reference was made to reported cases, and also to some specimens of the disease in the museum at St. George's Hospital.

Mr. HOLMES said that congenital growths were too often put down as nævi. There were many congenital growths which were mere outgrowths of cellular tissue resembling udder, some solid, some containing cysts. Some of the softer varieties of growths increased as rapidly as cancer, for which they might be mistaken. He had seen many such in the neck. In Mr. Venning's case he considered it a remarkable feature that it should have grown so rapidly after surgical interference. He could not account for the tension which occurred in the tumour when the child cried. He at first thought it was due to contiguity to the rectum, but it had no relation to the gut.

Mr. NORTON referred to the examination of the structure of a tumour by removing a small particle by means of a crochet needle through a fine trocar, and added that if such an examination had been made in the case under consideration it would have been recognised at once as a fatty tumour, and the operation for ligature of a nævus would then have not been performed. He referred to a case under his own care, in which a growth situated beneath the deltoid muscle was at once detected to be a fatty one, and was therefore removed. This growth protruded from the border of the deltoid when that muscle was brought into action, and produced cramping of the muscle and pains in the sholder-joint. It was quite impossible to say whether the tumour was a cyst or a *bursa*, or whether it was connected with the joint.

Mr. VENNING in reply said he considered the tension which occurred when the child cried was due to the extreme vascularity of the skin covering it.

THROMBOSIS OF THE CAVERNOUS SINUSES: SUDDEN LOSS OF VISION: HÆMORRHAGE INTO THE RIGHT ANTERIOR LOBE.

Dr. DOWSE read notes of this case. The patient, a strongly built man, in the prime of manhood, whilst walking home from Covent Garden, was suddenly tripped up behind, causing him to fall upon the back of the head. He was stunned for a few seconds, but recovered himself sufficiently to walk home, a distance of a quarter of a mile, without feeling giddy. There was no evidence of any serious injury to the skull, nor hæmorrhage, nor vomiting. The following morning, the scalp in the occipital region was much swollen; but he did not experience any severe pain in the head for two or three days, when it came on with great severity, and extended to every part. On the day previous to his admission into the Central London Sick Asylum at Highgate, his sight became cloudy, and in a few hours he was completely and (as it proved) permanently blind; so that, when first seen, there was nothing to be noted, either mentally or physically, save the total loss of vision. The other special senses were good, and both cranial and spinal nerves normal. The pupils were dilated, and the irides immovable. Upon ophthalmoscopic examination, the condition of ischæmia papillaris was well marked. The discs were swollen, œdematous, and covered with small patches of extravasated blood. The veins were large and tortuous. He was treated with blue pill and iodide of potassium; but the want of sight continued. On December 6th, he was seized with diffuse inflammation of the scalp; and on the day previous to his death the following note was made: "Is lying on his back in a state of partial coma. The lower limbs are devoid of voluntary automatic or reflex movements. The upper limbs are moved automatically. There is subjective, but not objective, cerebral consciousness. There are no convulsive movements, nor muscular rigidity, showing pretty clearly that his condition is not due to hæmorrhage over the convolutions." Thus was found a state of subconsciousness, cutaneous anæsthesia, muscular æsthesia, akinesis of lower and automatic movements of upper limbs. Pulse 160; temperature 104.2. The post-mortem appearances of the brain were stated in detail. The superior longitudinal and lateral sinuses were free from thrombi; but the cavernous sinuses were almost completely occluded with fibroid masses adherent to their walls. In the substance of the right anterior lobe, there was seen to be considerable hæmorrhage of recent date, not localised, but distributed freely through it. At the outer part, it was punctiform; but towards the anterior fissure, in relation to the gyrus rectus, was a clot of blood about the size of an acorn. The microscopic appearances of the brain and optic nerves were then detailed. Dr. Dowse remarked, in reference to the plugging of the cerebral sinuses, how little we have to guide us in making a diagnosis as to the existence of this lesion; and from examinations which he had made, he was inclined to believe that thrombosis of these blood-channels was of more frequent occurrence than was usually supposed; and it became a question how far this part of the circulation might be interfered with, and yet the brain retain its physical and psychical characteristics. It appeared probable that, in the case under consideration, thrombosis of some of the sinuses took place shortly after the accident, and gave rise to the intermittent attacks of pain. That the sudden loss of vision, with rupture of the retinal vessels, was caused by the plugging of the cavernous sinuses, seemed probable; and, again, the hæmorrhage into the anterior lobe might be ascribed to the same cause. Hæmorrhage into the anterior lobe was of rare occurrence, and its diagnosis more difficult than that of any other. (Gintrac found that, in a total of 751 cases of hæmorrhage within the cranium, it occurred only in 17.)

Sir WM. JENNER remarked that punctiform hæmorrhages could only occur as a result of an impediment to the return of the venous blood.

Mr. HULKE said that in most of these cases there was a distinct pulsation leading to the belief that the disease was an aneurism, and Mr. Holmes remarked that noises in the head were also usual, to which Mr. Hulke added that he recollected a case in which the noise such as Mr. Holmes had referred to was so loud that the husband of the patient was unable to sleep with his head upon the same pillow. He believed the noise was produced by compression of the vessels by the clot.

Dr. SYMES THOMPSON spoke of the case referred to by Mr. Hulke, and corroborated his statement.

SURGICAL SOCIETY OF IRELAND.

THE third meeting of the present session was held on Friday evening, January 7th.

The President of the Royal College of Surgeons, Mr. EDWARD HAMILTON, occupying the chair.

After the minutes of the previous meeting had been read by Mr. B. WILLS RICHARDSON, Hon. Sec., and confirmed,

Dr. BARTON then read a paper

ON A CASE OF SPINAL INJURY,

which will be found on page 68.

In the succeeding discussion

The CHAIRMAN said that from the detail of symptoms which Dr. Barton gave, he was inclined to form a most gloomy prognosis. He really did not think there was the possibility of her recovery until he heard the sequel.

Mr. F. T. PORTER inquired whether any analysis of the urine had been made in this case, because such was of importance. Another point of interest was that in which Dr. Barton said there had been no retention of urine. During the last month he (Mr. Porter) had had, he was sorry to say, a fatal case of spinal injury, and he was told by the patient that she had passed urine regularly, but on going

into her room one morning he found the bed wet. In explanation the patient told him that she had passed a quantity of urine, and, thinking it might be an overflow, he passed a catheter, and drew off about two tumblerfuls of very fœtid urine. He thought they ought not to be guided by the statements of patients as to their passing urine, because it might be the result of mere overflow. Another question which he desired to ask was, what value Dr. Barton placed on strychnia, when, of course, the acute symptoms had subsided?

Dr. HENRY KENNEDY said that the question of the evidence in such cases that had been raised was probably about the most difficult that could now engage the attention of the medical man in the public courts. His impression of the case recorded was, from the history of it, and from what he had read in Mr. Erichsen's book, that there was nothing at all of hysteria in it from beginning to end. It had all the symptoms that had been detailed by Mr. Erichsen so ably. The gradual progress of the symptoms was quite enough to show that the disease was a real one, and not one of mimicry, as Sir James Paget had called it. He (Dr. Kennedy) would be curious to know whether the administration of mercury was pushed as far as salivation. It was not so extraordinary that the effect of the injury was a slow form of inflammation which graduatly spread up the spine the whole way and implicated finally vision itself and the nerves which went to the eye. Under that impression, he thought mercury would be a most judicious plan of treatment—the best that could by possibility be used, and Mr. Erichsen specially mentioned that bichloride of mercury was a medicine of the greatest possible value in these cases. He thought Mr. Erichsen also alluded to the fact of the loss of vision being an early or late symptom as being one of considerable importance. If loss of vision occurred early in the case it was a more favourable sign than if it resulted several weeks or months after the occurence of the accident. He merely wished, in conclusion, to know whether mercury was pushed to salivation in this particular case.

Dr. BARTON, in reply to Mr. Porter's question, said that the urine was frequently examined, but no albumen was detected in it, nor indeed was there any material change in its characteristics. It presented none of the appearances which were usual in cases of direct injury to the spine, nor was it retained. The fact was, that merely the power of expelling it appeared to have diminished. Strychnia was never given—for this reason, that the patient could take no medicine by the mouth; vomiting was so constant that he could not calculate on giving any medicine by the mouth. With regard to what Dr. Kennedy had asked as to the administration of mercury, he (Dr. Barton) might say that inunction was the method in which it was used, partly for the irritability of the stomach, and it was perseveringly used for about six weeks, but no salivation occurred, nor any appearance of it. Loss of vision came on very gradually and rather early in the case, he thought, after a lapse of about four weeks from the commencement of the symptoms, which in those cases was early.

Mr. SWANZY then read his paper

ON A CASE OF TRANSPLANTATION OF THE CONJUNCTIVA OF THE RABBIT TO THE HUMAN EYE,

which will be found on page 67.

In the discussion which followed,

Mr. F. T. PORTER wished to ask Mr. Swanzy whether the sensibility in the transplanted part of the conjunctiva continued to be as well marked as in the rest of the conjunctiva?

Mr. SWANZY said that the sensibility in the transplanted portion of the conjunctiva as soon as it became pink was as good as the rest of the conjunctiva, but as long as it remained grey the patient did not feel it when touched lightly with the point of a probe. He might add that the proceeding he had detailed in his paper was of great use in a condition which often arose—he dared say perhaps a very similar condition to that which was found in his own patient, although not so extreme—where the general sac of the conjunctiva became too small, and the artificial eye had no proper place to rest, and had gradually become pushed up, and it was impossible to get any artificial eye to fit those eyeballs after a certain time. In those cases the proceeding he had narrated in his paper was adopted with great success by Wecker and others.

Dr. HENRY KENNEDY then read his paper,

A CASE OF CHRONIC RHEUMATIC ARTHRITIS OF THE HIP-JOINT.

which will be published in our next.

The Society then adjourned.

VIVISECTION.

VIVISECTION is a subject which a certain class of agitators is not likely to let drop. It is not our intention to enter the lists with them at present, as we hope before long to take a full and dispassionate view of the *whole* question; but we cannot help making a few remarks *in* reference to the very inopportune and intemperate *letters* that have recently appeared in the columns of the *Times*—one from that benevolent and highly-respected lady, the Baroness Burdett-Coutts, the other from Mr. Auberon Herbert.

The letter of Mr. Herbert is not merely remarkably verbose and rambling, weak in argument, one-sided, inflated, and flavoured with what the *Times* has very justly called "cant and rant"; it is something worse. It is altogether, from beginning to end, a tissue of gross misrepresentations. It is crowded and disfigured with such aspersions upon the moral character and feelings of scientific men as will not bear a moment's examination, and which are so unjust and devoid of foundation that we had scarcely the patience to wade through the whole of the letter. In answer to the question why he should select scientific men for his attack, while he overlooks commoner forms of cruelty, he says it is because they "count as a greater force in the future of society," and that when they defend vivisection they are "an educated and intelligent force on the side of cruelty." We have no wish to endorse the *tu quoque* retort that has been made use of by those who have protested against this outcry against one particular form of cruelty; but the hollowness of Mr. Herbert's argument has been well shown in the short and pithy rejoinder of Sir Henry Thompson. If the only fault of Mr. Herbert's letter consisted in the looseness of his arguments and the recklessness of his statements, we should not have much reason to complain; but the aspersions to which we have just referred, and the description he gives of the moral feeling, the work, and

the aspirations of scientific men, not only betray on his part great ignorance of the subject, but show that, however humane he may be to the lower animals, he is remarkably illiberal and unjust towards his own species. We little suspected that such reckless assertions could be made by one who cannot be ignorant of how much men of science have done towards the advancement of civilisation and in promoting the comfort and welfare of mankind. To say that "under the new gospel of knowledge all means and all instruments are sanctified," that the experimentalist thinks it his duty to discover at any cost and at any sacrifice of morality, and that we invite our censors to "look upon pain, not only as a secondary matter, but even as a good action for the convenience of special studies," are random statements which show in the writer a great lack of better argument, and which are calculated to discredit rather than to advance the object that he has in view. But Mr. Herbert does not stop here. He goes so far as to say that he and his followers are "called upon to face a revolt of a part of science against the authority of morality," that science has "practically repudiated any connection with the moral science of civilisation," that it is the humour of science to renounce all law higher than its own, "and that it lived less for the glory of God than for the making of personal reputations!" The utter untruth and recklessness of statements like these must be so patent to any one at all acquainted with the daily work, the aims, the singleness of purpose, and even the private character of most scientific men, that we ought to apologise for laying before our readers such absurd and groundless assertions. To attempt to refute them would be a task only too easy, but one of supererogation. Such rash aspersions—and we have by no means exhausted the list—carry with them their own refutation; and as we are not now addressing the general public, but those only who know how unjust they are, we shall take no further notice of them.

Mr. Herbert is anxious that his readers should understand the issues which are raised by the controversy about *vivisection*; but it is just in this very respect that he is *most* at fault. He would have the public believe that it really has "to face a revolt of science against the authority of morality;" that unless it makes a stand the hospitals and other places will be the daily scenes of the most outrageous tortures; and that "we are entering upon a battle which has to be fought out by the nation itself!"—and all this in face of the fact that painful experiments are either of rare occurrence, or are performed while the animal is under the influence of chloroform, and while he is himself obliged to admit that "this method of research has scarcely been acclimatised as yet in England."

We yield to no one in our love for the lower animals, and in our repugnance to the causing of any kind of harm to them that could possibly be avoided. But when we reflect that the cruelty of which our censors complain is not, even were it as they represent it, one hundredth part of that which is in other ways inflicted upon animals, and which they themselves sanction or connive at, we are at a loss to find language sufficiently strong to express our contempt for this hysterical shriek of humanity which some are indulging in—some, we might say, who are so anxious to pull out the mote which is in their brother's eye, while they do not see the beam which is in their own. With regard to the letter of the Baroness Burdett-Coutts, we are inclined to speak in the same terms that are used in speaking of the faults or mistakes of heirs apparent, and to say that we do not so much blame that estimable lady as we do her "advisers" for the indiscretion and injustice which characterise her letter. It is scarcely just to make hospitals responsible for what some of their staff may think proper to do in the course of their own scientific researches, and to call them institutions "in which the dissection of live animals is practised." As we have just seen, even Mr. Herbert admits that the practice of vivisection has scarcely gained any footing in our hospitals, and the cases in which, even under the influence of narcosis, experiments are made upon animals are so exceedingly small, that it was hardly necessary to require a guarantee from hospital authorities that no portion of the sums accruing from the Hospital Sunday Fund should be spent upon such experiments. In fact, so little is practical physiology studied in this country, so little of that science is learnt from a study of dead, much less of living, bodies, that original investigation has never been carried on to any great extent, and we are often twitted, especially by our Continental neighbours, because we learn our physiology and pathology more from books than from direct observation of nature. And, lastly, a little consideration might have shown those who are raising such an outcry against vivisection that the period allotted to students for the study of their profession is so short, the curriculum embraces so many subjects, and the teachers themselves have so much work on their hands, that there is really very little opportunity for experimenting on living animals—a method of investigation which takes up a great deal of time, which is attended with many difficulties, and which cannot by any possibility be practised except by those few men who are so devoted to the advancement of their special department of knowledge as to spend their time, and often their health, in original research.

THE ANTI-VACCINATION LEAGUE.

THE very same battle is being waged against vaccination that used periodically to rage in the life time of the immortal discoverer of the practice in the first quarter of this century. Now, as then, there are a certain number of persons who do not seem capable of understanding what Jenner has accomplished for the race, and who seem to remain in a chronic state of horror at the idea that matter should be taken from one infant and inoculated into the arm of another. There is a distinguished professor of Latin in the ranks of the Anti-Vaccination League who also makes himself notable by his vegetarian principles—a man of great literary ability, but without any practical acquaintance with medicine, who seems to have his mind filled with the horrors said to arise from vaccination. In his imagination, and in that of his fellow anti-compulsory vaccination leaguers, all kinds of diseases are habitually caused by vaccination. Epilepsy, phthisis, skin diseases, paralysis, and indeed every disease to which humanity is liable, are attributed to the beneficent discovery of Jenner. Fortunately it is the

prerogative of demonstrable truth that it is all the more strengthened by opposition. It is almost a pity that Government could not organise a body of men to protest against vaccination, against bank-notes, or policemen, in order to give society at large the advantage of hearing again and again what are the arguments for the prevention of small-pox, for paper currency, or for order in the streets. This function is, however, performed by the members of the Anti-Compulsory Vaccination League, as far as vaccination is concerned, and, were it not for the tragical consequences to individuals which arise from listening to these agitators, in all probability their opposition proves useful in arousing the medical profession to greater energy and care in practising vaccination.

Among the numerous cases recorded, where humble parents have been persuaded by these opponents of the Acts to brave the consequences of infringing them, we notice that of Frederick Keen, a dairyman, living in Notting Hill, who appeared some little time ago at the Hammersmith Court to answer six adjourned summonses to show cause why his children should not be vaccinated. On a former occasion the defendant set up a defence that five of the children had had small-pox, the illness being of three or four days' duration only. He also said he was his own doctor, and was guided in the treatment by a work by Dr. Coffin. The summonses were adjourned for the children to be examined.

Two children now attended with his eldest child, and produced a certificate from a medical gentleman stating that he had examined the boy, and was of opinion he had had small-pox. On this Mr. Shattock, the vaccination officer for Kensington, said he believed the medical gentleman was connected with the Anti-Vaccination League.

Mr. Bridge said the certificate was not legal evidence.

The defendant then called Mr. Thomas Charles Pearce, who said he was a surgeon, but not registered. The reason was that the orthodox mode of treatment was defective, and being so persecuted because he was a homœopathist, he could not reasonably associate with the orthodox school. He was a legally qualified practitioner, as he was a member of the Royal College of Surgeons. He had been in practice for thirty years, and had seen a great deal of small-pox. He had seen the child, who had scars of small-pox of a mild form. The scars might either be from small-pox or chicken-pox. If small-pox, the illness would have been more than three or four days. Chicken-pox, said the witness, might be mistaken for small-pox.

Dr. M'Cann was called by Mr. Shattock, and stated that he knew of many cases of small-pox where it would not be necessary to confine the patient to bed for one day. A child might have small-pox and only be ill for three or four days. From an examination of the defendant's child he thought it impossible to say whether or not he had had small-pox. It was, he added, quite impossible for so many unvaccinated children in one family to have slight attacks of small-pox.

Mr. Bridge, the magistrate, said the Act was passed under the conviction of the Legislature that it was necessary for the public safety that children should be vaccinated. He had nothing to do with the question whether it was right or wrong, and had simply to carry out the Act. The onus of proof that the child had been vaccinated, or had had small-pox, rested with the father. The defendant said his children had had small-pox, and he alone attended upon them; that he studied Dr. Coffin's book, and had sufficient knowledge to judge that it was small-pox. In corroboration he called a gentleman of experience; but it was quite clear from his evidence that the child had suffered from chicken-pox and not small-pox. He then made an order for five of the children to be vaccinated within fourteen days. With respect to the sixth child the summons was withdrawn, as it was not in a fit state of health to be vaccinated.

During the first twenty years of the 19th century the practice of vaccination by Jenner and his disciples kept England nearly free from any epidemic of small-pox; but of late years, it must be remarked, one epidemic has succeeded another with great rapidity. Non-vaccination and carelessness, with neglect of adult revaccination, are doubtless the main causes of this grave error in hygiene. As to the host of diseases set down to vaccination, after due attention has been given to all the arguments of opponents, it is on all hands admitted that the only disease clearly attributable to it is syphilis. A few years ago even that disease was said, in this country at least, never to have been spread by vaccination; but now, in 1875, we presume that even the most sceptical have at length admitted the possibility of that calamity occurring, even to experienced vaccinators.

It was this knowledge that syphilis might occasionally be spread by vaccination which led to the use of heifer vaccination, now so commonly made use of in Belgium, and which the recent debate in the Medical Society of London has so tended to popularise in this country. It certainly does seem fair that, in all states where vaccination is compulsory, as it is in this, those parents who have an over-sensitive dread of syphilitic contagion might be allowed to have their children vaccinated from the calf, as they do in Brussels. Compulsory vaccination, like compulsory education, is doubtless destined to become the practice of all civilised states. Government, we hold, has a right to force all who bring children into being to provide them with food, clothing, and other necessaries of life, among which reading and protection from small-pox are surely to be included.

The *experimentum crucis* for vaccination was more easily made in the days of Jenner than it will ever be again. In his time the practice of inoculation was in vogue, and a disciple of Jenner, after vaccinating an infant, would in a week or two inoculate it with small-pox virus, which, when the patient was successfully vaccinated, produced no effect. If the anti-vaccinators of our modern days could but get this one fact instilled into their minds, it might perhaps teach them what medical men mean by a prevention of disease. In the domain of hygiene there is nothing at all comparable with the powers of vaccination as a preventitive of small-pox. Were scarlatina or measles as easily prevented as variola, we might indeed boast of our positive acquisitions in the science of medicine.

THE DUBLIN HOSPITAL SUNDAY DISTRIBUTION.

THE Report of the Distribution Committee was presented last week. The Committee have adhered to the plan of distribution adopted last year, with one modification—viz., that they have raised the value of extern maternity cases by allowing 200 instead of 500, such cases to count as equivalent to one bed maintained throughout the year. The Committee having ascertained that there was a sum of £3,780 to the crédit of the fund, it was determined to distribute the sum of £3,450 among the participating hospitals :—Two-thirds of the sum (viz., £2,300) to be distributed according to the amounts of voluntary contributions received during the past year, and the remaining one-third (viz., £1,150) to be divided on the basis of the number of beds maintained by the amount of subscriptions received by each hospital during the preceding year. The cost of each bed has been computed on an average of the expenditure of the three preceding years. The Committee have made the following awards, viz. :—

	1875.			1874.		
	£	s.	d.	£	s.	d.
Sir Patrick Dun's ...	341	14	3	335	17	5
City of Dublin ...	613	16	2	1,160	17	2
Steevens' ...	213	4	3	312	0	4
Meath ...	677	17	4	—		
Mercer's ...	236	17	0	387	18	10
Whitworth (Drumcondra)	77	16	3	—		
Coombe (Lying-in) ...	155	9	9	215	2	7
Rotundo (Lying-in) ...	281	1	8	407	1	10
St. Mark's (Ophthalmic) ...	202	10	2	59	18	7
National Eye and Ear Infirmary	81	1	10	—		
Convalescent Home ...	430	18	11	—		
Cork Street (Fever) ...	137	12	5	121	3	3
Total ...	£3,450	0	0	£3,000	0	0

The more equal character of the distribution this year will be observed, which is due to the participation of the Meath Hospital and Convalescent Home, both of which institutions have, up to the present, been chiefly dependent for their income upon voluntary contributions.

The outcome of the Dublin Hospital Sunday movement this year appears to be, on the whole, encouraging, inasmuch as there may be said to have been no diminution in the disposition of the public to contribute. The £3,450 divided this year represents the charity contributions of nearly fifty churches more than were represented by the £3,000 allocated in 1874, and there is therefore no real growth in the benevolence of the Dublin public such as the figures would seem to indicate. The distribution, moreover, has a more equal look, and the anomaly is no longer presented of one hospital carrying off one-third of the entire fund from its sixteen equally meritorious fellow-workers. The glaring injustices of the old system of distribution are, however, still manifested ; for it may be observed that, as last year, the institutions which do the best work amongst the destitute sick of Ireland receive only a small fraction of the fund, while those which do least for the poor, but are in greatest favour with the rich, are handed over three-fourths of the money. If any unprejudiced citizen of Dublin were asked to name three hospitals which are specially known for their usefulness and for the extent of their charitable work, he would probably point to Mercer's, Steevens' and the Rotundo ; and if he were asked to indicate two others (of those which participate in the movement) which have, as far as the sick poor are concerned, "little to do and plenty to get," he would put his finger at once on Sir Patrick Dun's and the Convalescent Home. How are we expected to chorus the jubilation of the Committee when we have examined the distribution of the public charity to these two classes of hospitals ? We find that the three hard-working and over-taxed institutions receive each £243, while the two opulent and easy-going hospitals receive each nearly £400 ; and the very principle of the distribution is such that, as long as that principle be acted upon, the bulk of the fund must go to hospitals which live by begging, not by work.

The Committee has, however, departed from the method of distribution adopted in 1874 in one respect. It has given a higher credit and a larger grant for extern maternity cases than it did last year, and we are reminded by this circumstance to inquire to what hospitals such maternities are attached. We find only two—Sir Patrick Dun's and Steevens'—and it is thus obvious that the already replete revenues of the former hospital will thus receive an additional reinforcement.

We have already remonstrated with all our force against so inequitable a method of distributing the public charity, and we repeat our protest against a system which to such an extent disregards the actual working value of hospitals. We repeat our complaint that the fund is not distributed to those hospitals which afford the largest amount of medical relief to the poor, or apportioned in ratio of the amount of useful work done by each hospital, but is, on the contrary, freely appropriated amongst hospitals which are not in the position to meet the requirements of the majority of the sick poor, to the neglect and injury of those institutions which bear "the burthen and heat of the day."

COOKING FOR THE ARMY AND NAVY.

THE ingratitude with which those at the head of the Government of this country invariably treat inventors and public benefactors is proverbial. We were inclined to believe that no branch of the public service could produce so many conspicuous examples of official neglect of recommendations for the preservation of health and life as members of the medical profession. It does appear, however, that inventions for the improvement in cooking for the army and navy must be reckoned among those things that the Government and those charged with the duty of providing good and nutritious food for our soldiers and sailors, seem to regard with the supercilious air of a junior clerk of the War Office.

Ten years ago Captain Warren, R.N., observing that the ordinary mode of cooking, both by roasting and boiling, involved a large amount of waste and loss of nutritious material, set to work to remedy this, and after a series of expensive experiments, introduced to the notice of the authorities a novel system of cooking, by means of an ap-

paratus simple in construction, and which not only prevents loss, but attains a desirable object in the culinary art, that of securing the largest amount of the most valuable and palatable portion of meats without loss of flavour by soaking in water or burning, and at an extraordinary saving of fuel. Captain Warren's apparatus is a closed receptacle, around which the steam of boiling water freely circulates. The meat is placed in an inner chamber, the outer case of which is heated by water kept at the boiling point, and is cooked in its own vapour; but the heat to which any food is subjected never exceeds 210 degrees Fahr. In April, 1865, this invention was fairly tested in the kitchen of the Cambridge Barracks, at Portsmouth, in the presence of Major-General Lord William Paulet and the officers of the staff, and all acknowledged that there was a marked superiority of the food in every way. The soup was decidedly of richer flavour, the meat more tender, and the gravy richer. As regards the baked rations, they were decidedly superior. The economy also was marked. It is estimated that the loss of meat by ordinary methods of cooking is about one-third by roasting, and rather less by boiling. A leg of mutton weighing 12 lbs., cooked in Warren's apparatus, lost only three-quarters of a pound; when taken out it weighed 11¼ lbs. On questioning the soldiers to whom the rations were served, the reply was unanimously in favour of the soup, of the *bouilli*, and of the mutton; of their superiority in quality and in flavour to the ordinary cooked rations. The experiments were repeatedly tried and conducted in a most searching manner by command of his Royal Highness the Commander-in-Chief, and always with results which showed that if this mode of cooking were adopted the gain in a national point of view would be enormous—that the saving to the nation in the consumption of meat alone would at least amount to £2,750,000 per annum. With respect to economy of fuel, many trials were made for the purpose of testing the apparatus in this respect. At Aldershott it was seen to be superior to Deane's in—1st, as effecting a saving of fuel amounting to 50 per cent.; 2nd, in labour of attendance; 3rd, in saving food; 4th, in improving the quality of the food; 5th, in expenses—first cost of fitting up cooking-house. Having seen Captain Warren's apparatus fairly tested for some time past in hospital, we can vouch for the saving effected in these several particulars, and feel convinced that if adopted for ordinary domestic cooking a material saving, both of fuel and meat, must be the result. The saving of fuel would be not only individually, but in the aggregate, very large. Taking the average cost of fuel for cooking purposes during the summer months alone, when fires for heating are not required, at 6d. per diem, and it is fairly estimated that it would effect a saving in London alone of nearly two millions worth of coals annually.

Captain Warren subsequently turned his attention to the victualling of the soldier, a subject particularly demanding attention from those interested in the health of the army. He prepared a "campaign biscuit," containing meat, to take the place of the unwholesome salt pork and biscuit, for service in the field. These were highly spoken of, and Sir Richard Airey proposed to the War Office that Captain Warren should be rewarded, receive a special appointment, and become associated with Professor Abel in conducting experiments for the purpose of improving the dietary of the troops in time of war, and of rendering them independent of salt junk. This proposal was, however, rejected at the War Office, and to the present moment, and in defiance of the recommendation of the Duke of Cambridge that Captain Warren should be suitably remunerated for the benefits he has conferred on the country, the soldier, and the sailor, we are told that that gentleman is to be "left in the undisturbed enjoyment of his natural privilege of paying his own expenses."

Notes on Current Topics.

Women Graduates at the University of London.

At a meeting of Convocation at the University of London the admission of women to degrees was brought under consideration, and elicited a discussion which may turn out to be one of great importance. It was moved by Mr. A. P. Hensman "That it is desirable that a new charter be granted to the University, and that no such charter will be acceptable to Convocation which does not enable the University to grant degrees in Arts to women."

The motion met with general approval, but fortunately for the female sex there were many present who objected to the insertion of the words "in Arts," and a resolution was carried omitting those words.

It will be for the Senate next to consider that resolution, and though hitherto the majority of the Senate have been of opinion that it is not advisable to admit women to degrees, yet since the discussions that have taken place in the lay and the medical journals, and at the meeting of the General Medical Council, some members of the Senate have changed that opinion, and we shall not be surprised to hear that the Senate have adopted the resolution sent up to them from the members of Convocation, in which case it will be open for women to take degrees not only in Arts, but also in Law and Medicine.

Mortality of Infants in Russia.

Official statistics show that in Russia out of 10,000 infants 3,830 die before they have completed the first year, 975 the second, and 524 before the third. Out of 1000 children only 655 are alive at the end of five years. Probably the extreme rigour of the climate causes such fearful mortality among the younger population, and undoubtedly the system of baby farming which is carried on by the State to a great extent contributes largely to swell that death-list which it was intended to diminish. The foundlings, who are admirably looked after by the officials in establishments of this kind to be met with in the various towns of Russia, are, after completing a few years in the institute, sent out to peasant women in the villages. The little ones are often very kindly treated, but it can never be expected that a woman will take as good care of another person's offspring as of her own.

House Foundations.

On Thursday last a deputation waited upon the Home Secretary with the view of urging upon the Government

the necessity of introducing some measure to prevent the present system of building upon insecure and unwholesome foundations.

Dr. Tripe, as one of the deputation, said that the worst results were seen in diseases such as consumption and fever arising from houses being erected on rubbish shoots. The good brick earth was taken away, and the vilest rubbish took its place. He had tried all in his power, as medical officer of health, to prevent such deposits, but had failed owing to magistrates holding that they must prove injury to health of some individual passer-by, which, of course, it was impossible to do. In South Shields the medical officer's report said that large deposits had been made, and injury to health had resulted. In Leicester the medical officer found the high death-rate due largely to an annual visitation of infantile diarrhœa in those parts of the town built on such refuse. Drs. Parkes and Sanderson say that in Liverpool the practice was one of the probable causes of the unhealthiness of the town. They had advised the Town Council not to allow excavations to be used for the reception of refuse unless it was efficiently drained. Medical officers generally held that the offensive matter in cinders should be dry before use, and the only way to secure this was by efficient subsoil drainage ; that as the vegetable and animal matter was nearly dried up the cinder decayed and disappeared in about three years, and was virtually innocuous before that time. They further recommend that places filled up with cinder refuse should not be built on for two years from the date ef the last deposit ; and also that road scrapings should not be mixed with cinder refuse. His own opinion was that it should be made illegal to erect buildings over these deposits, and that a condition should be imposed, whereby a layer of sufficient good concrete to the satisfaction of the district board and the surveyor of the board should be used, so as to secure that the concrete would offer adequate resistance to the admission of any foul air into houses. He considered also that all drain-pipes going under houses *should* be laid in concrete, owing to the very common fact that pipes gave way and emitted smells of a most contagious character.

Mr. Sclater-Booth remarked that in the country they had bye-laws which placed the remedy in their own hands.

Mr. Cross, the Home Secretary, promised to think over what appeared to be a serious and growing evil before committing himself to a distinct promise.

New Coroner's Court.

A NEW Coroner's Court House, situate at 15 South Wharf Road, adjacent to St. Mary's Hospital, was opened by Dr. Hardwicke last week, so that inquests in that district will no longer be held at the neighbouring public-houses.

Advisability of Lectures on Insanity in Medical Schools.

WHEN referring to the increase of insanity in Ireland the inspectors of lunatic asylums deduce its rapid extension within the past twenty years from the tables furnished by the English Commissioners, a rate of extension latterly much in excess to that of the progressive growth of the population. Between the three kingdoms the authenticated number of the mentally affected may now be set down as fully 90,000 human beings, or 18,000 more than in 1860. In the different universities and schools of medicine throughout the empire, we find professors of anatomy, surgery, botany, chemistry, &c., and teachers in physiology, and other scientific subjects of research, a knowledge of which is deemed requisite for an educated practitioner ; on the study of bodily diseases, common to man and the lower grades of animal creation, every attention and care are bestowed, while to that of the mind, its functions, its reaction on matter, and the reciprocal influence which physical ailments exercise over the mental faculties, little or none is given.

The inspectors refer to the opinion given forty years ago by the late Lord St. Leonards, when simply as Sir Edward Sugden, Lord Chancellor of Ireland, who, feeling the necessity which existed for a system of tuition in the treatment of insanity, proposed its establishment under Privy Council rules, subject, however, to the approval of boards of governors to district asylums, as on them would devolve all expenses incidental to the maintenance and salaries of clinical clerks. No practical action having been taken in furtherance of his Lordship's views, the matter rests in abeyance, and more perhaps to the detriment of individuals and of the general community, than the unobservant would be disposed to assume. The inspectors express the opinion that to open the wards of asylums to all medical students, by making their attendance compulsory, would be most injurious to the tranquillity and well-being of the insane, in fact, in any one institution there would not be space enough to accommodate a fifth of them as visitors, nevertheless, in our opinion at least, it would be highly advisable they should attend lectures delivered in schools of medicine by physicians of practical experience in the treatment of lunacy, certificates of which should be considered recommendatory in obtaining civil and military appointments.

Unqualified Practice.

IT would appear to be a hopeless task attempting to put a stop to unqualified practice, either by legal measures or journalistic influence, when our contemporaries admit the evil openly to their advertisement columns. For instance, in last week's *Lancet* we read an announcement—"To Surgeons, or well-up Non-Qualifieds who can get the co-operation of a Medical Man." A business "opened by the proprietor, a non-qualified seven years *who does well in practice and midwifery*," to be sold.—Address Veritas, *The Lancet* Office. Here is an unqualified man openly engaged in illegitimate practice, who boasts of having "several midwifery cases on the books," allowed to use the columns of a medical journal, and to flaunt his flag from an office which assists him in his unholy traffic. We pause !

The Clinical Society.

AT the annual general meeting of the above Society, held on the 14th inst., the report of the Council was read and adopted, and the following gentlemen were elected as officers and Council for the ensuing year :—President : Sir William Jenner, M.D., K.C.B. Vice-Presidents : Dr.

George Johnson, Dr. Murchison, Dr. Henry Thompson, Mr. Thomas Bryant, Mr. Christopher Heath, and Mr. Jonathan Hutchinson. Treasurer: Dr. Headlam Greenhow. Council: Dr. Bastian, Dr. Buzzard, Dr. William Selby Church, Dr. Andrew Clark, Dr. Dyce Duckworth, Dr. Hilton Fagge, Dr. Braxton Hicks, Dr. Moxon, Dr. Douglas Powell, Dr. Reginald Southey, Dr. William H. Brace, Mr. Brudenell Carter. Mr. Warrington Haward, Mr. George Lawson, Mr. Howard Marsh, Mr. Arthur Trehern Norton, Dr. Michael W. Rice, Mr. James Rouse, Mr. Edgcumbe Venning, and Mr. Soelberg Wells. Honorary Secretaries: Dr. William Cayley and Mr. Thomas Pickering Pick. Mr. Hulke moved, and Dr. Cholmeley seconded, a vote of thanks to the retiring secretary, Dr. Southey, who briefly replied. This was followed by a vote of thanks to the retiring vice-presidents and the other members of the Council, proposed by Dr. Broadbent, and seconded by Mr. Norton.

During the evening it was announced that the Council had proposed that Mr. Cæsar Hawkins, F.R.S., should be elected an honorary member of the Society. It will be remembered that recently Sir Thomas Watson and Dr. C. J. B. Williams were chosen honorary members.

Pharmacy in Ireland.

We referred last week to a somewhat impertinent letter addressed by the Irish Pharmaceutical Council to the Secretary of the English Society. A new light is thrown on the epistolary style of the Irish Council by a paragraph which we find amongst a record of its proceedings in the last issue of the *Chemist and Druggist*. It is stated that "the Clerk to the Council remarked that he had received about twenty letters which required answers, and asked was he to send replies. The President directed him to acknowledge the receipt, and say they would be considered at the next meeting."

This method of doing business on the part of the Irish Council is consistent with its proceedings, but hardly either polite or business-like.

Comparative Cost of Maintenance in Asylums and Poorhouses of Lunatics.

If not impossible, it would be very difficult indeed, and the Irish Inspectors of Lunatic Asylums consider of little practical use, to arrive at the exact amount which 3,140 insane located in no definite mode and under no fixed regulations in 153 workhouses cost during the year for their immediate maintenance, entailing as they do a very fractional portion of the general expenditure, and the more so as not unfrequently they are found diffused through these establishments, mixed up with, and living among the ordinary paupers. Taking, however, one union with another, from local inquiries they compute that £11 a head would in round numbers be the closest approximate calculation, if so, the expenditure on them as a body in 1874 might be set down at £34,450; whereas were they resident in district asylums, they would have incurred an outlay of £79,160, the cost therein of each patient, including the rate in aid of £10 8*s*., being £25 2*s*. for that year.

Dr. Tilt has been elected an Honorary Fellow of the Obstetrical Society of Philadelphia.

Death from Chloroform in Dublin.

We regret to learn that a death from chloroform took place on Saturday last at Dr. Steevens' Hospital. The patient was a young and apparently healthy man, and was undergoing an operation for phymosis by Mr. Hamilton when he suddenly developed symptoms of syncope which, with all the efforts of the surgeons in attendance, could not be averted. We hope to give further particulars next week.

Earl Granville has accepted the Presidency of the Dover Hospital, and promised to assist the institution in every way in his power.

Her Majesty the Queen has been graciously pleased to appoint John Thomas Banks, Esq., M.D., to be a Member of the Senate of the Queen's University in Ireland in the room of Robert Adams, Esq., M.D., deceased.

Lord Napier of Magdala, the Commander-in-Chief in India, while at a parade of the troops at Delhi on the 8th inst., was thrown from his horse, and had his collar-bone broken by the fall. His lordship is doing well, and his condition gives no cause for uneasiness.

The Football contest between the London United Hospitals and Liverpool, in the result of which considerable interest has been manifested, came off on Saturday last at Kennington Oval. The Londoners proved themselves much the stronger team, and gained a hollow victory.

By the will of the late Mr. Bishop, of Chepstow Villa, Notting Hill, St. Mary's Hospital, St. George's Hospital, Middlesex Hospital, Charing Cross Hospital, St. Bartholomew's Hospital, the Royal Free Hospital, Brompton Consumption Hospital, St. Thomas's Hospital, and the Small-pox Hospital each receive a legacy of £1000.

It has been decided that medical officers upon attaining the rank of surgeon-major, will not in future be required to provide at their own cost a capital case of surgical instruments; but all executive medical officers will have to provide themselves with, and keep up at their own expense, a case of pocket instruments of an authorised pattern, which will be shortly approved. This case is to be carried in the regulation pouch.

The County and City of Cork Medical and Surgical Association will meet this (Wednesday) evening at 8 o'clock, p.m., at the Royal Cork Institution, when the following communications are set down for reading:—

Dr. H. M. Jones, on "Eyeball containing Segment of Percussion Cap."

Dr. Atkins (for Dr. Cremen), on "Sacculation of Aorta—Pin-hole Rupture—Sudden Death" (specimen).

Dr. H. M. Jones, Discussion on paper on "Anæsthetics."

Prof. O'Connor, "The Effects of Alcohol on the Nervous System."

A post-mortem examination made last week upon the

body of a lunatic patient in the Prestwich Asylum led to the discovery of no fewer than 1,841 articles in his inside, viz.:—1,639 shoemaker's sparables, six 4-inch cut nails, nineteen 3-inch cut nails, eight 2½-in. cut nails, eighteen 2-inch cut nails, forty ½-inch cut nails, seven ⅝-inch cut nails, 39 tacks, five brass nails, nine brass buttons, 20 pieces of buckles, one pin, 14 bits of glass, ten small pebbles, three pieces of string, one piece of leather three inches long, one piece of lead four inches long, and one American pegging awl—the total, 11lb. 10oz.

Another fatal instance of the growing practice of ladies taking narcotic medicines without professional advice formed the subject of an inquiry before Mr. Carttar, coroner, at Greenwich, last week. It appeared that an independent lady, named Eliza Moore, æt. 59, who resided at Greenwich, told her servant to bring her medicine which she had been in the habit of taking; and on the girl again going into her bed-room she found the bottle (containing a liquid chiefly composed of laudanum) empty and her mistress very ill. Dr. Pink was in immediate attendance and resorted to the most active means to avert a fatal result; but without success.

The Rev. Dr. Bartle, principal of the Freshfield College, near Liverpool, was charged last week with refusing to vaccinate two of his children, æt. eight and eighteen months respectively. The case was instituted by the board of guardians of Southport, who pressed for the utmost penalty, as Dr. Bartle was guilty of wilful non-compliance with the Vaccination Act. The doctor pleaded guilty, and said he had conscientious scruples against vaccination, as he believed it did more harm than good. One of his children was now suffering from the impure lymph introduced into its system. The magistrate fined him 20s. and costs in each case.

The extension of the libraries and museums of the Royal College of Surgeons in Ireland, which has been for some time under consideration, and for which competitive plans were obtained last year, has at length been decided upon. The contracts for the work have been signed by the President and Council and Messrs. Hall, of Harcourt Street, Dublin, the contractors. The present library is to be lengthened to the extent of about two-thirds its present length, and widened by about 15 feet, and above it a museum of the same size is to be buit in communication with the present museums. The cost is to be £5,000, and the work is to be completed within a year, under the superintendence of Mr. Symes, the College architect.

SENTENCE ON A QUACK.

The untimely tender-heartedness of judges and magistrates in dealing with medical swindlers as compared with their severity towards rogues of other classes has been a great discouragement to those who have undertaken to deal with such vagabonds. It is therefore gratifying to be able to record an exemplary punishment administered to a quack in Belfast last week by Mr. Otway, the Chairman of the County of Antrim. The subject of his sentence was James Graham, a quack doctor, who had been going amongst the working classes of the town imposing upon them worthless medicines, and representing himself to be a medical practitioner, he being unqualified. His worship delivered a lengthened sentence, in the course of which he said it was no excuse for the prisoner that others had traded and traded successfully by similar falsehoods on the strange credulity of mankind, and that others who call themselves professors of health should, by the marvellous power of high-sounding advertisements throughout the world in which they mixed, by proposing to cure by means of some pills, and to cure all sores by means of some ointment, amass immense fortunes. They announced that their cures were of universal value, and if the public were willing to believe the lie they suffered accordingly. But the prisoner's plan was not confined to advertisements. He travelled from place to place, announced by circular and by placard that he was a doctor, gave columns of certificates, all of them identical and signed by different names. The certificate for use in Edinburgh was the same as that for use in Belfast, the first purporting to be signed by some person named Frazer, and the second by a man named Arnold, of Dublin. He made local visits from house where he had reason to think people were unwell, telling them in most cases they had a disease called "Wolf on the Liver," persuading persons that they were unwell, and in all cases that were alleged against him, inducing them to take his medicine, promising them speedy recovery, telling them he would call again, taking their money, and never calling. He said he did not think he was guilty of a crime in selling the medicine. He (his worship) did not believe that, but the crime to which he had pleaded guilty was that he feloniously pretended that he was a qualified physician and was not, that he knew and could cure diseases of which he was totally ignorant, and by this means abstracted money from the poor. The sentence of the court was that he be imprisoned for twelve months.

THE VACCINATION ACTS.

At Bow Street Police Court, on Jan. 22, a woman was summoned before Mr. Flowers on a charge of neglecting to have her child vaccinated. Mr. Yardley, on behalf of the St. Giles's district, prosecuted, and said that since the first occasion on which the defednant attended the court she had caused the child to be vaccinated, and the summons would be withdrawn on the defendant paying the costs. This the defendant declined to do. She produced the child, and called attention to the swollen and inflamed state of the arm and an eruption on the face, which appeared since the vaccination had been performed. The child had also had several fits. Mr. Flowers said the child certainly appeared to be in a dreadful state, and he could only account for it by the fact that vaccination had been performed while the infant was in a bad state of health. Mr. Yardley said, of course, under the circumstances, he would not press for the costs, but would pay them out of his own pocket. The summons was then withdrawn.

It is a pity Mr. Flowers did not confine himself to simply deciding the case, without hazarding his opinion upon the child's disease. A little consideration or inquiry might have shown him that it was possible the child's symptoms had nothing whatever to do with vaccination. It did not occur to him that skin eruptions and fits commonly arise from many different causes, and that certainly it would be difficult, if not impossible, in most cases, to trace any form of "fits" to vaccination. It is to be regretted that magistrates let fall observations of this kind, since they are eagerly caught at and used by the anti-vaccination agitators in encouraging their ignorant followers to break the law. An instance in point, which would be amusing were it not for the sad reflections on the pernicious ignorance of certain agitators, was recently exemplified in an anti-vaccination circular. A great point was there made of the fact that Mr. Simon had demonstrated that the *inoculation* of tubercle was possible, the writer of the circular

being apparently unaware of the circumstance that the term inoculation could apply to the use of any other material than vaccine lymph, and that Mr. Simon's remarks referred to the inoculation of tuberculous matter alone. and in no way to the vaccine virus. We need not tell our readers that no evidence whatever exists even of the possibility of transmitting tuberculous disease through vaccination. There can be no objection to persons outside of the profession discussing questions like vaccination, and informing themselves upon it ; and indeed, the more the public know about these matters the better ; but it would at least be a subject for congratulation if persons of some education, like certain of the anti-vaccination agitators, such as those who penned the circular in question, would, before throwing their energies into such a movement, acquire a knowledge of the fundamental facts of the subject upon which they strive to influence public opinion.

THE MEDICAL COMMISSIONERSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

Referring to this subject, the *Lancet* says: "The question of the suppression of the Medical Commissionership is much discussed among the profession in Dublin. It is discussed first with regard to the injurious policy which such suppression would imply, a policy as fatal to the thorough efficiency of central public health administration as the suppression of medical officers of health would be to local public health administration. Next it is discussed with regard to the particular individual whom the profession had looked to as the proper successor to Dr. M'Donnell. In view of this latter gentleman's resignation there is a singular unanimity of feeling among medical men in Dublin, equally entertained, it may be said, in London, that it is especially to be desired that he should be succeeded in the Commissionership by Dr. Rawdon Macnamara."

We have good reason to believe that a strong effort is being made in the Local Government Board office and on the back stairs of Dublin Castle to push two of the *employés* of the Board into comfortable berths at the expense of the country and of the doctors. Mr. Henry Robinson, a non-medical inspector is—it is stated—to have a new place made for him as Assistant Under-Secretary at the Castle, in order that his place in the L. G. B. may be emptied for the occupancy of a *protégé* whom it is desired should (like Doub) be "taken care of." We are most concerned to hear the rumour that if Dr. Croker King should get the Medical Commissionership his place as Inspector is to be filled by a nameless non-medical clerk in the office, and one more thus subtracted from the already weak medical staff of the department. There is nothing certain about the ultimate arrangements except the conclusion—inevitable in all matters of Dublin Castle patronage—that pets will be provided for and the necessities of the public service entirely disregarded. From the very fact that the rumour to which we have alluded violates every sense of justice and expediency, we think it likely that it is true.

DISPENSING FRAUDS.

The exposure of the malpractices of certain dispensers in Sheffield by the public analyst, in which the omission of or subtraction of the most potent remedies from medical prescriptions was brought under notice (with which our readers are doubtless familiar) has created an absolute uproar, not only in the pharmaceutical journals, but in the leading journals of the kingdom, in the latter of which a virtuous horror has been evoked which is rather amusing to those who are acquainted with the real state of the medicine trade. It seems to be new light to the newspapers that a prescribed medicine does not always contain either in quantity or quality what the medical adviser has ordered, and that medical men are not uncommonly obliged to be content with an approximation to the exact effect which their treatment is expected to attain. The pharmaceutical journals are virtuously indignant with the analyst for having exposed the nude verity of the dispensing trade, and have enrobed themselves in a garb of innocence which, after their attitude about the Adulteration Act, sits rather unfittingly upon them. For instance, we find in the *Pharmaceutical Journal* the following phrase :—"There is no room for reticence, and we are unreservedly in accord with the argument used by one of the writers, that if the publican who fortifies his beer with noxious drugs offends against morality no less than against law, *this is still more the case with the chemist who sophisticates his drugs or deliberately dispenses medicines without the proper proportions of the remedies ordered.*" This enunciation is rather out of place in columns which have but a few weeks ago been eloquent in apologies for the sale of citrate of magnesia without citric acid or magnesia and which were some months before lonely in denunciation of an Act intended to put down the rogueries practised by the vendors of "milk of sulphur" one-half plaster of Paris and scammony well fortified with adulterants.

The Sheffield *Daily Telegraph* points out that in the event of the case being proved, it will still remain to be ascertained where the fraud lies, whether with the druggist who actually made up the prescriptions, or with the manufacturers and dealers who supply the retailers of such articles as iodide of potassium and sulphate of quinine. This is quite true, and we are heartily glad that the analyst's outspoken report has raised a flutter of newspaper agitation, even though the matter will be no more than a nine days' wonder. It is manifestly too late to pretend pharmaceutical purity when it is a matter of notoriety that great fortunes are made by the sale of articles which are not what they profess to be, and by drug contracts for the supply of the refuse of the materia medica market—tinctures made with methylated spirit and all the rest of it—at enormous prices for the use of the sick poor.

At the December examinations of the English Society, a lady, Miss Isabella Skinner Clarke, passed the Major, and thus became, as far as examination can make her, the first lady "pharmaceutical chemist" in Great Britain. Miss Clarke intends to conduct a pharmacy in the West End. It should be added that she has studied for all her examinations at the South London School of Pharmacy, and has been successful on each occasion that she has presented herself.

Literature.

ON ADDISON'S DISEASE. (*a*)

This work consists of the Croonian Lectures of the Royal College of Physicians for 1875, and consequently its subject-matter is already more or less familiar to our readers. The lectures are now published in the form of a neat, well-printed volume. The original lectures are, however, supplemented by an appendix, containing detailed reports of 37 cases, selected from Dr. Greenhow's own practice, and from other sources. By such means a pretty perfect picture of this comparatively rare but very interesting malady is furnished. In a second appendix is to be found a list of 303 cases of more or less genuine Addison's disease, arranged in twelve groups, so as to give the reader a fair idea of the different associations with which skin-bronzing is found. The whole forms a complete treatise on the subject, and as such will take its place alongside other important monographs in the library of all practitioners who aspire to be thoroughly cognisant of their profession in its less familiar as well as its common aspects.

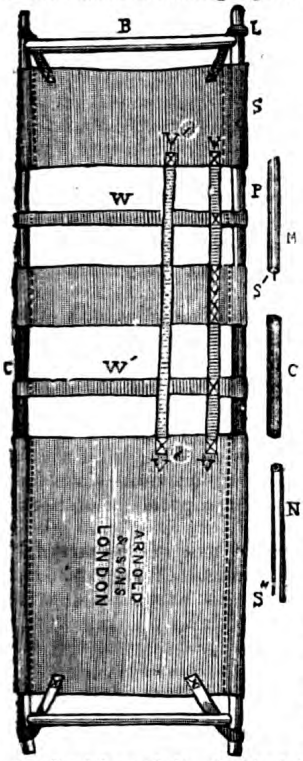
(*a*) "On Addison's Disease." By E. Headlam Greenhow, M.D., F.R.S., Physician and Lecturer on Medicine to the Middlesex Hospital. Longmans and Co. 1875. Pp. 212.

New Inventions.

DESCRIPTION OF A FORM OF STRETCHER.

By C. R. B. KEETLEY,
Assist.-Demonstrator of Anatomy at St. Bartholomew's Hospital.

IN many cases of typhoid and other fevers, of peritonitis and other inflammations, of bed-sore of various chronic diseases, in many surgical and obstetric cases, it is very desirable to have a mode of moving a patient from room to room or from bed to bed, and a mode of changing the patient's bed and body linen without causing the least avoidable disturbance or excitement. For such cases this apparatus has been contrived. The chief principles on which it is constructed are: 1. It can be placed under the patient piecemeal, and afterwards easily and without danger of mistake fitted together again. 2. It is only a skeleton of webbing in the part which sustains the back and buttocks, and thus allows bed-sores and blisters to be dressed. 3. The cutaneous sensibility of the back is so extremely blunt that the network of webbing, coarse as it is, feels like a whole and undivided piece. Its chief advantages are: 1. The most sensitive or feeble patient can be freely moved with no sense of discomfort and no dangerous disturbance. 2. Bed-sores and blisters on the back can be easily dressed through its means, and even the back percussed or auscultated through it. 3. Its details can be easily modified by any needlewoman to suit the necessities of particular cases without altering the apparatus in principle. 4. It is light and portable, it packs into a parcel three feet long and five inches in diameter.



In using it, s s′ s″ w and w′ are passed under the patient gently one by one, and the poles then slipped through the hems and loops. Two chairs, each having one of the cross-pieces B upon it, can sustain the patient while the bed is made, &c.

The stretcher has been used with satisfaction at the Queen's Hospital, Birmingham, and at St. Bartholomew's Hospital, London. It is made by Messrs. Arnolds, West Smithfield, London.

Correspondence.

MEDICAL ATTENDANCE ON THE CONSTABULARY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent A. B. has made a great mistake. Were I acquainted with him I would write privately; but as he appears under an anonymous signature, I can only address him through your columns, and in doing so, though unwilling to give offence, I must remonstrate sharply. He has offended against common morality by acting towards another as I have no doubt he would not wish another to act towards himself. He has acted against all the principles of medical ethics in attempting to deprive another of what are really private patients—at least, we must consider them as such until the law is altered—and I am only surprised that the Inspector-General let him down so easily in his answer. He has offended against the profession and himself by letting the authorities think that the attendance on the constabulary is so liberally paid for that it was worth while to do a shabby act to obtain it. I am similarly circumstanced with A. B., and would as soon have thought of sending a circular to my friend's private patients as to endeavour to oust him from a position which he has long and creditably held. A. B. can only be excused by the plea of youthful indiscretion and want of consideration.

It is quite right and fitting that in all new appointments the attendance on the constabulary should be given to the medical officer of the district; but to attempt to oust a person already in attendance is really too bad, and I am glad that the authorities were so considerate and consistent as to refuse to listen for a moment to the proposition.

I am, Sir, your obedient servant,
J. MARTIN.

DR. HARDWICKE AND CORONERS' INQUESTS.

THE following is Dr. Hardwicke's explanation—embodied in a letter to the Rt. Hon. Assheton Cross—why he considered it his duty to hold an inquest upon the body of the late Mr. Acton. As Dr. Hardwicke remarks, if a letter from the Home Secretary to him has been published, it is only fair that his explanation should be also made public.

Coroner's Office, Park Place Villas,
Paddington.

To the Right Hon. RICHARD ASSHETON CROSS.

In reply to your letter of the 21st inst., I have the honour to state that in the case of the late Mr. Acton I followed in every respect the usual course. I received instructions from the proper officer that Mr. Acton had been found dead in his bath-room on the morning of the 7th inst., and that he had not been seen by any medical man since the 29th of September last. The officer added to this information the fact that on calling at the residence of the deceased he was told by a relative that the death could not be certified, except after a post-mortem examination. The officer then called upon Dr. Hall Davis, to whom he had been referred as the last medical man who had seen the deceased. He saw Dr. Davis, who was unable to assign a cause for death, and who presumed that an inquest would be held. On this information from the officer being laid at my office in due form, with the usual request for an inquiry—26 hours after the death of Mr. Acton—a warrant was issued for the inquest, and an order was given to Dr. Hall Davis to make a post-mortem examination in accordance with the provisions of the Medical Witnesses Act. In compliance with this order, Dr. Davis gave evidence at the inquest upon the facts of the post-mortem, and received the usual fee for a post-mortem and evidence thereupon. In the evening of the same day, after the warrant for the inquest and the post-mortem order had been issued, and after the jury and witnesses had been summoned, and after the post-mortem had actually taken place, Mr. Acton, jun., called upon me, bringing a certificate from Dr. Murchison, who had been present at the post-mortem, and desiring to know if the coroner's inquiry could be avoided. I told Mr. Acton simply the fact that it was impossible for me to cancel the inquest unless the Registrar of Deaths felt he could accept the certificate. No further communication being made to me, the inquest took place the following day, as previously arranged. I have since learnt that the Registrar refused to accept the certificate on the ground of the coroner's warrant having been issued. You will see from these facts that no certificate or explanation accounting for death from natural or expected causes was made known to me until some hours after the Coroner's Court was called into action. The warrant was granted and the post-mortem order issued in the mode that is always adopted by the coroner in similar cases of sudden death, and upon like information as that laid by my officer in the present instance. The question raised in this case, in so far as the jurisdiction of the coroner is concerned, is whether a certificate of death given after the issue of a coroner's warrant, and after the post-mortem examination ordered by the coroner has been made, ought to supersede and cause to be set aside his public inquiry into the circumstances connected with the death. The question to my knowledge has never previously been raised, and it would have been a great relief to me in this instance, as an old personal friend of the deceased, if I could consistently with

my duty have answered it as the friends of the deceased wished. I gave the question my most careful consideration, and I came to the decision that, however pleasant it might be to personal feeling, and however it might smooth and ease the anxieties of my office to accede to such a request, the concession would be an innovation subversive of all past rule and precedent. But that which influenced me most was the fact that the departure asked for from the usual course in this case must be purely an exceptional act, applied to one case out of at least 300 similar cases of sudden death occurring in the district of Central Middlesex in the course of the year. I felt that if I granted this exception on personal grounds, or other grounds, it must necessarily be accepted as a precedent (unless it were concealed, which would be very wrong), and that I should experience, almost daily, the utmost difficulty in holding inquests at all; and I felt also that such precedent might be used to thwart an inquest where inquiry is of the utmost importance to the public interest, and to private interests in cases where property is concerned. The coroner of a large district is daily conversant with these difficulties in relation to sudden deaths; he knows how readily and fatally he might be misled, if on private information, or questionable certificate of death, he were to allow an inquest to be cancelled or set aside. He feels, therefore, that so long as the present rules for the registration of deaths remains, he has no truly safe course open to him but to carry out his inquiries in open court, without distinction of class, and in accordance with the long-established usages and precedents of his office. It was in this spirit, and none other, that I allowed the inquest to proceed in the case of the late Mr. Acton.

I have the honour, &c.,
W. HARDWICKE,
Coroner for Central Middlesex.

NIGHT SENTRIES.

A HOSPITAL surgeon writes in reference to the comments upon night sentries in an evening newspaper urging in effect that men can be hardened and rendered more fit to bear exposure to wet and cold by being constantly exposed to them, and also that it is legitimate in time of peace to subject soldiers to hardships which are then unnecessary, in order to discover and weed out those who are more weakly than the rest.

The first part of this contention rests upon an error once widely prevalent with regard to the nature of the influence which is exerted by habit upon the human organism. Because muscular strength and fitness to undergo certain kinds of muscular exertion my be increased by training, it is assumed that the power of resistance to depressing agencies may be increased by resisting them. Nothing can be more fallacious than such an argument.

The night duty of sentinels is liable to be injurious in two chief ways—first, by its interference with the sleep which is necessary to the maintenance of health; secondly, by the influence of cold and wet in chilling the surface of the body. The power of resisting cold is simply a matter of consumption of fuel, and depends upon the power of the digestive apparatus to receive and assimilate sufficient food to produce the necessary amount of animal heat. Now the digestive functions are not rendered more active by exercise, except within narrow limits and for a short period of time; and any one, under increased exertion, or unusual exposure to cold, or the abandonment of alcohol, experiences an increase of appetite, will speedily find that such increase is neither permanent nor progressive. The digestion is mainly governed by the nervous system, and the nervous system is soon shattered by broken rest. To deprive a man of a considerable portion of his sleep and then to expose him to cold is simply to exhaust his reserve of vital force, and to push him half way towards the goal of a complete breakdown. In the case of sentry duty in time of peace over empty palaces and offices deserted by all but housekeepers, the physical evils are heightened by the feelings of disgust and weariness which are associated with them. In time of war, the mental tension will do much to sustain the bodily frame against hardship; but there is no fatigue so depressing as that produced by labour which is necessarily barren of results. "Sentry-go" in London stands in this respect on the same level as shot drill.

Apart from theoretical considerations, the history of shipwrecks, and of other circumstances which have demanded proendurance, proves that such endurance has invariably been displayed in the highest degree by those who had not previously been called upon for any similar effort.

The practice of weeding out the weakly men of the brigade by testing them to the breaking point, if it is actually pursued, may be cited as affording an entirely new illustration of the survival of the fittest in the struggle for existence, and its cruelty will be thought by many persons to deserve, at least, some share of the attention which is being bestowed upon the vivisection of the lower animals. That the idea is not wholly imaginary may perhaps be shown by the following extract taken from the official Report on the Health of the Army which has just been issued:—

"In the Foot Guards, the highest ratios of admissions (to hospital) of deaths and of invaliding are combined in the 1st Battalion of the Grenadier Guards stationed at London and at Windsor."

Obituary.

MR. GASCOYEN.

IT is with deep regret that we announce the death of Mr. George Green Gascoyen, member of the Board of Examiners of the Royal College of Surgeons of England, Surgeon and Lecturer on Surgery at St. Mary's Hospital and Surgeon to the Lock Hospital.

On the Monday he commenced his duties with pride and pleasure at the first meeting of the newly-constituted Board of Examiners at the College, when he appeared to be suffering from a bronchial catarrh. On Tuesday the symptoms increased in severity, and on the Wednesday he found it necessary to absent himself from the Examination. He died on the Sunday morning after a short attack of pleuro-pneumonia, having previously suffered for some two years from obscure symptoms of disease of the lung.

The career is thus cut short of one of the most able and promising of the younger school of surgery. His election on the Board of Examiners was a sufficient recognition of the estimation in which he was held by the leading members of the profession, but it was only one among many such which his labours had evoked.

He held the important office of Dean of St. Mary's Medical School for some years, in which capacity his earnestness in the working of the institution, his judgment in the direction of the students, and the unfailing amiability of his disposition were strikingly displayed, and on his retirement the good-will of the students was evinced by the presentation to him of a magnificent testimonial in silver.

Mr. Gascoyen held also the distinguished post of Honorary Secretary to the Royal Medical and Chirurgical Society.

His contributions to medical science, which are numerous, though not embodied in the form of a work, consist of valuable papers in the Transactions of the Societies, and in the pages of contemporary literature.

His name may be placed among the very few who had not an enemy—publicly well known and respected, in private life beloved and appreciated by the numbers who had the pleasure and privilege to call him a friend.

DR. WILLIAM LANE, OF NEWTOWN-LIMAVADY.

ONE of the most respected medical practitioners of the north of Ireland has been removed from the sphere of usefulness which he had occupied for fifty years in his place of residence, and his death has been regarded with a unanimity of sorrow which it falls to the lot of few men to elicit. He died on the 13th of January, and having been born on the 24th of June, 1804, was just about completing his 72nd year. He had held the appointment of medical officer to the Workhouse and Fever Hospital since their foundation with unremitting attention to his duties and with equal credit to himself and satisfaction to the guardians, gaining for himself at the same time a high

public character for his surgical adroitness and his ability as a physician. He was for many years coroner of the district. The local papers of all politics give expression to the universal regret. No death, says the *Londonderry Sentinel*, for the last forty years in this part of the country has evoked so much public sorrow. For Dr. Lane was no ordinary man—large-hearted, sympathetic, and tender, his name was a household word. He was not only looked up to with confidence as a man of skill in his profession, but regarded as a warm friend. Approachable at all times —morning, noon, or midnight—kind and genial in manner, and generous in disposition, he was always as ready to attend to the requirements of the humblest member of the community as to that of the most wealthy. Hundreds of visits he paid to, and hundreds of prescriptions he made up for, the poor and needy, without receiving one farthing of remuneration; and when in many instances he would be asked, "What was to pay?" or, "How much have I to give you, doctor?" his reply would often be, "Dear, just buy yourself some beef with the money to help your constitution."

In the Workhouse, of which he was medical attendant, he was equally beloved; his visits were always welcome; kind words and kinder deeds alleviated many a pain and soothed many a sorrow. But although in general practice he was first among physicians in the treatment of his patients, he was pre-eminently successful as an accoucheur; in that branch of his profession he had no superior. As a citizen he was ever ready to give his help and assistance in "works of necessity and mercy." He was for many years Chairman of our Town Commissioners, and took considerable interest in all improvements that were for the health and comfort of the people.

Active in his habits, and loving his profession, he often attended to the wants of others when he himself required rest. We may say he died in harness, for his last illness was contracted a few days ago by going out at midnight to visit a patient in the country.

It is proposed to raise a memorial to his memory, which, it is suggested, should take the shape of a Memorial Clock Tower on the New Town Hall of Limavady.

For ourselves, we may say that we have known Dr. Lane almost since the establishment of the MEDICAL PRESS, now nearly forty years, as a zealous, painstaking practitioner, and a most conscientious public officer, and as one who has never consented to purchase public approbation or personal advantage by the sacrifice of any good professional principle. *Oh, si sic omnes!*

Medical News.

Vital Statistics.—From the Registrar-General's returns we learn that during last week 5,855 births and 4,067 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1,000 persons living. The annual death-rate was 24 per 1,000 in London, 31 per 1,000 in Edinburgh, 27 in Glasgow, and 33 in Dublin. The annual rates of mortality per 1,000 during the same period in the other large towns were—Brighton 20, Sunderland 21, Plymouth 24, Norwich 28, Nottingham 28, Bradford 29, Hull 26, Leicester 20, Bristol 27, Portsmouth 23, Sheffield 26, Birmingham 25, Wolverhampton 25, Leeds 24, Newcastle-on-Tyne 27, Oldham 31, Liverpool 35, Manchester 33, and Salford 40. The annual death-rate from the seven principal zymotic diseases averaged 4·0 per 1000 in these towns, and ranged from 1·0 and 1·5 in Brighton and Plymouth, to 6·6 and 10·6 in Liverpool and Salford. Nine fatal cases of small-pox were returned in Manchester and Salford, whereas not one occurred in any of the other towns. Small-pox, measles, scarlet fever, and whooping-cough are all somewhat fatally prevalent in the borough of Salford. Enteric fever caused 9 more deaths in Sheffield. In London, the 1,590 deaths included 60 from scarlet fever, 16 from different forms of fever, 14 from diarrhœa, and not one from small-pox. The deaths in the zymotic class were eighteen below the corrected average number from the same diseases in the corresponding week of the last ten years.

The Hospital Saturday Fund.—The Metropolitan Hospital Saturday Fund, which is principally contributed to by the working classes, and of which Capt. Mercier is chairman, held its final meeting last week. A fresh committee will be elected, who will have the control of the fund for the current year. At this meeting Mr. Vincent Mercier was presented with a silver inkstand as an acknowledgment of his gratuitous services. The meetings held by the working men who are dissatisfied with the present administration were considered, and resolutions condemning them passed. A second audit of accounts was also gone through, and satisfaction expressed that the total receipts for the year had been £5,473 19s 8d., whilst the expenses were £577 less than the previous year. Votes of thanks were passed to the Chairman, the Treasurer, and the Hon. Secretary, and the meeting separated.

Society for Relief of Widows and Orphans of Medical Men.—A quarterly court of the directors of the Society was held on Wednesday, January 12th, by the kind permission of the Royal Medical and Chirurgical Society, in their rooms, Berners Street. In the unavoidable absence of the President, Mr. J. G. Forbes, Vice-President, presided. At the meeting grants amounting to £1,143 were made to 57 widows, £52 were voted to 13 children, and assistance was given to 4 children from the Copeland Fund, making a total of £1,220 10s. The expenses of the quarter were £66 11s. The applications of 2 widows and 1 child for grants were accepted, and 1 child was added to those receiving assistance from the Copeland Fund. Four new members were elected. The resignation of Mr. Renton, the collector, was announced, and on the motion of Mr. Fuller, Acting Treasurer, it was resolved that the Secretary be empowered to apply for and receive future subscriptions. A printed notice to be sent to every member half-yearly.

Gleanings.

The Relation of Physicians to Life Insurance Companies.

THE French Central Association of Physicians have passed the following resolutions in reference to Life Insurance Companies:—

1. To refuse always and absolutely to deliver any certificate or attestation whatever concerning the health of their habitual patients, even when they are solicited by the latter, and of however satisfactory a character such certificate might be. 2. To refuse also, when medical officers of companies, if they are requested by such companies, to examine their own patients, and to cause such examinations to be made by other practitioners. 3. To use all their influence with any of the companies to which they may be attached in order to obtain a revision and simplification of the list of questions that have to be replied to. But this list once adopted, every care should be taken to reply to them in the most clear manner, so as to aid the company in determining whether to accept or refuse the assurance.

How to Strap the Breast.

STRAPPING the mammary gland is of avail to prevent and arrest lactation. But, remarks Dr. W. W. Munson, in the *New York Medical Journal*, strapping will be of no use unless it is well done. Let the first strip be put on so as to hold the breast well up by itself alone, whichever direction it is made to take. I usually commence by placing a strip laterally beneath the breast, about half-way between the nipple and lower margin, draw the gland well up, and attach one end high up on the sternum and the other end high up under the arm. The next strip is placed at right angles to the first, close to the nipple. Apply to breast first, draw it well up and fasten upper end, letting it pass over the shoulder, then draw down lower end firmly and fasten it. Don't skip the nipple or cover it, but cut holes through the strips that pass over it, and let it project through. This is to allow the milk which may ooze out for the first few hours to escape, without burrowing beneath the plaster, pushing it off, and making a hot, disagreeable, irritating poultice. Several thicknesses of soft cloth should be placed over the nipple (when pervious), to absorb the milk that escapes. This should be renewed as often as it becomes saturated.

A timely application of this plan of strapping I have found almost sure to arrest commencing mammary abscess.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. A. T. H.—The subject is fully gone into in our issue of December 29th, 1875.

Dr. J. A.—1. Certainly. 2. Many thanks; the information will be useful at the proper time.

The following account of Mr. Birch's death is given in a private letter: "You have of course heard before this of the murder of Mr. Birch, but you are probably not aware of the circumstances of fiendish atrocity which attended the outrage. Mr. Birch went up to Perak in order to post some official proclamations. While having his bath he sent his native interpreter to post them up. The man fastened two up, but the people at once tore them down again, whereupon he returned to Mr. Birch to ask what he should do. The latter told him to put them up as fast as they were torn down, and this the interpreter did until he had posted no less than seven, when he lost his temper and struck one of the natives with a cane. He was immediately killed, and the natives then ran in a body to Mr. Birch's bath-room, which was built on two floating logs. His orderly, who was at the entrance, presented his gun, but seeing he could not stop them, he cried out to Mr. Birch to save himself, and jumped into the river. Mr. Birch dived down between the two beams, and on coming up feet foremost on the other side the fore parts of both his feet were cut off by the instep. He dived again and tried to swim to his boat, but he was struck again, and both heels were cut off with a sword stroke from one of the natives. He was then captured, taken on shore, and speared through the neck to the ground, after which he was stabbed about a dozen times in various parts of the body. Even after this horrible torture he lived some hours. Next day Capt. Innes and two other officers, and a small body of men of the 10th Regt. went up to try and recover the body of Mr. Birch, together with his documents, &c. In attacking a stockade Capt. Innes was killed, and the two other officers with eight men wounded. The party had then to retire and wait for reinforcements."

Quekett Microscopical Club.—On Friday evening next, at 8 o'clock, Mr. A. Hammond will introduce "A Comparison between the Metamorphoses of the Crane-fly and the Blow-fly."

Clinical Society of London.—On Friday, at 8½ p.m., Dr. Bell Taylor, "On a Method of Operating for Cataract by which the Pupil is Preserved"; "On a Method of treating Obstinate Cases of Symblepharon by Replacing the Ocular Conjunctiva by Skin." Mr. C. Heath, "On a Case of Gunshot Wound of the Arm, dividing the Brachial Artery and the Median Nerve." Dr. Broadbent, "On a Case of Embolism of the Right Posterior Cerebral Artery, with Yellow Softening of the Occipital Lobe of the Hemisphere; Death from Endocarditis." Mr. Pugin Thornton, "On a Case of Œdema of the Larynx."

UPPINGHAM SCHOOL.

To the Editor of the Medical Press and Circular.

Sir,—As I am receiving numerous letters from medical attendants, parents, and others, asking me to inform them whether it is safe to send scholars back to this school on the 21st inst., I should esteem it a favour if you would allow me to state through the medium of your journal that I have no evidence before me as to whether or not the necessary structural alterations in the different houses have been completed, and the recommendations on my report, which was read on Saturday last only, as to the *final* disinfection of the infected houses have been carried out.

I certainly cannot recommend the return of the scholars until I have reason to believe that everything has been done that I consider necessary to insure the safety of the boys.

I am, Sir,
Your obedient servant,
Alfred Haviland,
Medical Officer of Health to the Uppingham Rural Sanitary Authority.

Northampton,
17th January, 1876.

Smart.—Our American contemporary the *Clinic*, in its number for January 1st, opens with the following: "We present to our readers this morning with salutations for this New Year's Day, 1876. We present it with the same salutations to many who are not our readers, that seeing what they have lost in years gone by they may hasten to make provision for the future." We trust our American *confrères* will estimate the *Clinic*, not only to the extent of its own trumpeting, but at its true value, and support it accordingly. It is not a large journal, but what there is of it is generally very good class, which to our way of thinking is preferable to huge publications, three-fourths of which are generally padding.

Dr. Lane, Bishops-Castle.—Letter arrived as we were going to press; will be noticed in our next.

M. A. B.—Will appear in our next.

Sir William Jenner, Bart., is the newly-elected President of the Clinical Society of London.

Prof. Huxley will lecture at the Royal Institution on Friday evening next "On the Border Territory between the Animal and Vegetable Kingdoms."

Mr. Bruce will please receive our best thanks.

Medical Practice in China.—We learn from an exchange that a Chinese doctor in Hong Kong, who had failed to save the life of a patient, was tied to the corpse as a punishment, and was only released on his agreeing to pay all funeral expenses.

Communications, Enclosures, &c., have been received from—Mr. George Gray, Speenhamland. Dr. Hoblyn, Bath. Dr. Tilt, London. Dr. Harrison, Audlem, Cheshire. Dr. Hammond, New York. Dr. McGrigor Croft, St. John's Wood. Dr. Kelly, Rotherhithe. Dr. Meadows, London. Dr. Lloyd Davies, Abergele. Dr. Bodman, Devizes. The Registrar-General. Mr. W. Parker, Bath. Mr. E. S. White, Fowey. Dr. Abrath, Sunderland. Mr. Keyworth, Cirencester. Mr. Alderman Cox, Brighton. Mrs. Fayrer, London. Mr. Shackelford, Husbands Bosworth. Dr. Black, Cockburnspath. Mr. Keetley, St. Bartholomew's Hospital. Mr. Blackett, Society for Relief of Widows of Medical Men. Dr. Drysdale, London. Dr. Johnson, Dublin. Dr. Handsel Griffiths. Dr. Martin, Portlaw. Farre, London. Dr. Cortis, Caterham. Mr. Royle, London. Mr. Haynes Walton, London. Mr. Cockcroft, Hurworth. Mr. Fleming, Chatham. Dr. Julius Althaus, London. Mr. Froste, Dublin. Dr. Williams, Manchester. Dr. Hughlings Jackson, London, &c., &c.

VACANCIES.

North London Consumption Hospital.—Physician. Honorary. (See Advt.)

Royal Free Hospital, Gray's-Inn-Road.—Three Junior Resident Medical Officers. Board and residence provided. (See Advt.)

London Hospital.—Assistant Obstetric Physician. Full particulars of the Secretary.

West London Hospital.—House Surgeon. Salary, £70, with apartments. Applications to the Secretary.

Finsbury Dispensary, Clerkenwell.—Physician. Honorary.

Wantage Union.—Medical Officer for the Wantage District. Salary, £50, with fees extra. Address the Clerk to the Guardians, Wantage, Berks.

Birmingham General Dispensary.—Resident Surgeon. Salary commencing at £130 per annum. Applications to the Secretary.

Royal Cornwall Infirmary, Truro.—Visiting Surgeon. Address the Secretary.

Stratton Union, Cornwall.—Medical Officer for the South District of the Union. Salary, £60, with extras. Applications to the Clerk of the Board of Guardians.

Amersham Union.—Medical Officer for the Second District. Salary, £70. Applications to the Clerk of the Board.

Liverpool Dispensaries.—Assistant House Surgeon. Salary commencing at £108, with residence, &c. Address the Secretary, 34 Moorfields, Liverpool.

Applecross.—Parochial Medical Officer. Salary, £154, with house. Address the Chairman of the Board, Tullick, Lochcarron, N.B.

APPOINTMENTS.

Bickerstaffe, R., M.D., House Surgeon to the Darlington Hospital.

Bowkett, W. D., M.R.C.S.E., Resident Medical Officer to the Bolton Union Workhouse at Fishpool.

Carline, W. A., M.B., C.M., M.R.C.S.E., House Surgeon and Dispensary to the Lincoln County Hospital.

Gobat, J. T., L.R.C.P.Ed., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 5 District of the Wrexham Union.

Jackson, P. J., M.R.C.S.E., House Surgeon to the Surrey Dispensary, Great Dover Street, London.

Kenny, J. H., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for No. 3 District of the Parish of Birmingham.

Macan, A. V., M.B., M.C., Gynæcologist to the City of Dublin Hospital.

Sloan, S., M.D., C.M., an Assistant Physician-Accoucheur to the Glasgow Lying-in Hospital.

Tandy, B. L., L.R.C.P.Ed., L.R.C.S.I., Medical Officer and Public Vaccinator for No. 4 District of the Risbridge Union, Suffolk.

Willan, R. M., M.R.C.S.E., Medical Officer for the No. 4, or Leigh District of the Martley Union, Worcestershire.

Wood, T. O., M.R.C.P.Ed., F.R.C.S.Ed., Resident Medical Superintendent of the Isle of Man Lunatic Asylum, Douglas.

Marriages.

Burroughs—Evanson.—On the 15th inst., at Nenagh Church, Hastings W. Burroughs, L.R.C.S.I., to Ada Kathleen, daughter of the late Rev. A. M. Evanson.

Fergus—Brereton.—On the 13th inst., at Moira, co. Down, S. Fergus, M.D., Moy, to Mary, youngest daughter of the late Wm. Brereton, Kilwarlin, Hillsborough.

Deaths.

Blake.—On the 14th Jan., at Richmond, Surrey, W. J. R. H. Blake, M.D., aged 46.

Cottingham.—On the 9th Jan., at Mare Street, Hackney, E. C. Cottingham, M.R.C.S.E., aged 50.

Cronin.—On the 17th Jan., at Queenstown, W. J. Cronin, F.R.C.S.

Doherty.—On the 11th Jan., at Redcastle, Donegal (after an illness of only two days), Richard Doherty, M.D., J.P.

Lambert.—On the 15th Jan., at Bootham, York, Thos. Tyas Lambert, M.R.C.S.E., aged 65.

Marsh.—On the 17th Jan., at Dante Road, Newington Butts, Thos. J. Wm. Marsh, M.D., aged 56.

Noott.—On the 12th Jan., at Cardigan (after a lingering illness), Wm. L. Noott, M.R.C.S.E., aged 71.

Stutter.—On the 17th Jan,, at Upper Sydenham, F. A. Stutter, M.D., aged 49.

Stewart.—On the 11th Jan., at Cootehill, Cavan, Wm. Stewart, M.D., aged 79.

Valentine.—On the 4th Jan., at Malden-Newton, Dorsetshire, John Valentine, M.R.C.S.E., aged 77.

IRISH POOR-LAW INTELLIGENCE.

MEDICAL EXAMINATION OF LUNATICS.

At a recent meeting of the guardians of Ballinasloe Union, a communication from the clerk of petty sessions at Eyrecourt was read, asking payment of 5s. for car hire and 20s. as fee to Dr. Pelly, who had examined a lunatic at Shannon Grove, in the Ballinasloe Union district, on a magistrate's order, on which occasion a car was procured for the purpose of conveying the patient to Eyrecourt for the examination. It was agreed to write to the Local Government Board to ascertain if payment of the money was compulsory ; also whether the medical officer of the district was not the proper doctor to be called upon. At the last meeting of the guardians a reply from the Local Government Board was read. It was to the effect that if Dr. Pelly was called on by the magistrates to inspect the patient the guardians were liable for payment.

BOYLE GUARDIANS.

The minutes of previous meeting having been read, in which reference was made to Dr. Kisby's application for a fee he claimed under the provisions of the Compulsory Vaccination Act, for having assisted in prosecuting defaulters at Ballyfarnon petty sessions, the application was refused by the guardians, on the ground of no expense being incurred in the case by the medical officer of the dispensary district. Dr. Kisby attended before the board, and produced printed documents to show that fees were granted to himself and other medical gentlemen in similar instances ; a magistrate's certificate was also produced in support of the claim. A communication was since then received from the Irish Medical Association stating that should the guardians refuse paying Dr. Kisby the fee demanded by him legal proceedings will be instituted for recovery of same.

Chairman—Will the money be paid to Dr. Kisby ?

Clerk—The Board declined to reply to the letter.

The former ruling of the Board remains unaltered.

NAAS UNION.

THE LATE ELECTION OF A MEDICAL OFFICER FOT KILCULLEN.

A letter from the Local Government Board on the above subject was read, sending communications which have been addressed to them in reference to the recent election of a medical officer for the Kilcullen dispensary district, in which it will be seen that the legality of the constitution of the committee of management is questioned. The following is the letter :—

"Gentlemen,—I beg leave to lay before you the following statement of facts :—

"An election of medical officer for the Kilcullen dispensary district was held yesterday. Sixteen members and four candidates attended. Nine votes were given for Dr. Barker and seven for me. It was so well known before then how each member would vote that a tie was expected. One of those who voted for Dr. Barker stated, as I am informed and believe, that he did so because if he had voted or me the Chairman would give a casting vote for Dr. Barker, and that therefore his so voting for Dr. Barker and not for me did not affect my prospect of appointment. It is a mistake to suppose that the Chairman, who had already voted for Dr. Barker, could give a second or casting vote contrary to Article XV. of your General Order.

"I have reason to believe that three of the persons who voted for Dr. Barker should not have voted at all in consequence of not being qualified under the provisions of the Act. I therefore charge that the dispensary committee of Kilcullen seems to be illegally constituted. That persons voted for Dr. Barker who appear not entitled to vote. That the improper admission of even one of those votes gave a false appearance of equality to the members voting for Dr. Barker and myself, and led directly to a majority of votes for Dr. Baker. And I respectfully submit for your consideration that if you find even one improper vote to have been so given for Dr. Barker, the interests of justice require a new election. —I have the honour to be, gentlemen, your obedient servant,

"D. J. Buckley, B.A.,
Physician and Surgeon."

Protests were also made by the parish priest and a number of the ratepayers on the same grounds.

BALLINA GUARDIANS.

SMALL-POX.

Dr. Mahon stated that there were two cases of small-pox in his district, at Kilmurry ; one person died after a short ilness, and a young woman was now ill of the disease whose removal to hospital at an early stage of it he had counselled, but ineffectually. As it was most important that persons afflicted with small-pox should be removed to hospital, he wished to know how he was to proceed to attain so important an end.

Clerk—The magistrates can give an order for removal if it is shown that there is not suitable accommodation at the house of the person.

Dr. Mahon—In this case I found 3 cows tied in the room, which I ordered to be removed, but otherwise the house was large enough.

Mr. Walshe said that some of the family had come to his house for wine and other things ; he suspected that there was something peculiar in the disease, and learning it was small-pox he prevented them coming into the house. His brother issued a ticket to have the doctor attend, who found the disease to be the very worst type of small-pox.

Dr. Mahon said this woman was being attended by her brother only, and he told him he ought to get a woman to nurse her, as he was likely to get the disease himself, but he replied that he (the doctor) might himself be the first to take it.

Mr. Walshe—The family did everything possible to disguise the nature of the disease.

Dr. Mahon traced the disease to inoculation by a quack called "Jack tbe Doctor," who had visited the locality, and who said the persons had only mild attacks of the natural pock.

ATHY UNION.

STIMULANTS IN THE INFIRMARY.

THE Clerk then read returns prepared by him.

Chairman—The Clerk showed that there were 4,000 days last year more than in the previous year.

The Clerk said that each patient who remained in for a week counted as seven days.

Chairman—And about 2,450 more than the year 1873. The cost of stimulants in 1873 was £99 1s. 4d., in 1874 £97, in 1875 £179—that is, in 1875 the cost was close on double what it was in 1873.

Mr. Reeves—We should know how much more was the cost per head in 1875.

Chairman—In 1875 it was something about twopence per head, and in 1873 one penny and one-fifth.

The Clerk said that the cost was about 8d. 2-5th per head per week in 1873.

Mr. Byrne—Half of those in the infirmary get nothing, and others get two glasses of whisky a day.

Mr. O'Beirne—Could we not ascertain the exact number of patients who get stimulants?

Mr. Reeves—Or how many people were in the hospital last year?

Mr. Byrne said that he did not know whether the ratepayers could get two glasses of punch each day.

The Chairman said that the increase was a most serious matter. In 1875 the cost of all kinds of liquor was nearly five times higher than in 1872. He did not see what power they had in the matter except to call the doctor's attention to it.

The Clerk said that during the period from December, 1873, to December, 1874, 64 people died in the hospital. The number of deaths from October, 1874, to October, 1875, was 77.

The Clerk, in reply to Mr. Whelan, said that the number of deaths included the deaths in the fever hospital, but the returns of stimulants before the board only referred to the workhouse hospital.

Mr. O'Beirne—It is useless for us to be trying to save the ratepayers if the doctor is not here to give us satisfaction. Now, after waiting a considerable time, I propose his absence be noticed on the minutes.

The Chairman put the resolution, which he declared carried.

Subsequently Dr. W. F. Mara came before the board, and said that Dr. O'Neill was very ill, and unable to leave his bed.

It was ordered that Dr. Mara's explanation of Dr. O'Neill's absence should be inserted on the minutes.

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING JAN. 15, 1876.

Total registered deaths in Dublin and suburbs *	...	197

" " Edinburgh ...	31	"

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week was 34, including 6 from fever (1 typhus, 3 typhoid or enteric, and 2 simple continued fever), 5 from scarlet fever, 7 from whooping-cough, 4 from diarrhœa, 3 each from measles and erysipelas, 1 each from diphtheria, croup, influenza, &c.

Eleven children died from convulsions.

Bronchitis proved fatal in 38 instances, pneumonia in 7, pleurisy in 1, and lung disease unspecified in 11.

Four deaths were ascribed to apoplexy, 2 to paralysis, 4 to cephalitis, 1 to epilepsy, and 3 to brain disease unspecified.

Heart disease caused 14 deaths, liver disease 3, hepatitis 1, and kidney disease unspecified 1.

Twenty-two persons died from phthisis, 2 from mesenteric disease, 4 from hydrocephalus, and 3 from cancer.

Five accidental deaths were registered.

Two deaths each from scarlet fever, whooping-cough, and diarrhœa, and 1 from measles were registered in Belfast.

Five deaths from scarlet fever, 3 from fever, 2 from whooping-cough, and 1 from measles were registered in Cork.

Three deaths from scarlet fever, 2 from whooping-cough, and 1 from measles were registered in Londonderry.

QUARTERLY SUMMARY.

Births.—In the Dublin District the number of births registered during the quarter ended on 1st January amounted to 2,128, being equal to 27 in every 1,000 of the population.

The number of births registered north of the river Liffey was 863, or 32 in every 1000 of the population, and south of the river the number was 865, or 25 per 1000. In the suburbs of Rathmines, Donnybrook, Blackrock, and Kingstown the number of births registered amounted to 400, or only 23 in every 1000 of the population.

There was registered in London during the same period an annual birth-rate of 35 in every 1000, in Glasgow 37 per 1000, and in Edinburgh 31.

Deaths.—The number of deaths registered in the Dublin Registration District during the quarter afforded an annual ratio of 1 in 36, or 28 in every 1000.

The number of deaths registered last quarter north of the Liffey was 805, or 30 in every 1000, and south of the river was 1,033, also affording an annual mortality of 30 in every 1000 of the population. In the suburbs of Rathmines, Donnybrook, Blackrock, and Kingstown the number of deaths registered was 333, being equal to an annual death-rate of 19 in every 1000 of the population.

The deaths registered in Belfast represent an annual ratio of 27 in every 1000, in Cork 32 per 1000, in Limerick 26, in Londonderry 25, in Waterford 25, in Galway 20, and in Sligo 19.

The number of deaths registered in London was equal to an annual mortality of 24 in every 1000, in Glasgow 25 in every 1000, in Edinburgh 23 in every 1000.

Diseases.—Dublin Registration District.—The deaths from zymotic diseases registered during the quarter amounted to 426, or 19·6 per cent. of all the deaths, and equalling an annual rate of 5·4 per 1000 of the population, the deaths from the seven principal diseases of this class being equal to 4·3 per 1000 inhabitants.

Whooping-cough was very prevalent—76 deaths, or 3·5 per cent, of the total deaths were referred to this disease. In the corresponding quarter of 1874 only 6 deaths were caused by whooping-cough.

Sixty-eight deaths, or 3·1 per cent., were ascribed to fever, viz., 13 to typhus, 44 to typhoid or enteric, and 11 to simple continued fever. Measles proved fatal in 67 instances, or 3·1 per cent. of all the deaths.

Diarrhœa caused 83 deaths, or 3·8 per cent. of the total deaths. Scarlet fever, which caused as many as 238 deaths in the corresponding quarter of 1874, contributed no more than 25 deaths during the past quarter. Croup caused 26 deaths, diphtheria 13, erysipelas 9, &c.

Convulsions caused 151 deaths.

Three hundred and thirty-five deaths, or 15·4 per cent.

of all the deaths, were referred to bronchitis, 58 to pneumonia, 5 to pleurisy, 4 each to laryngitis and asthma, and 55 to lung disease unspecified.

One hundred deaths resulted from heart disease, 4 from aneurism, 2 from pericarditis, 48 from apoplexy, 40 from paralysis, 10 from epilepsy, 9 from cephalitis, 6 from insanity, 1 from chorea, and 35 from brain disease unspecified; 29 from liver disease, 7 from jaundice, 1 from hepatitis, 16 from Bright's disease, 2 from cystitis, 1 each from ischuria and stone, and 20 from kidney disease unspecified.

One hundred and ninety-six persons fell victims to phthisis, being 9 per cent. of the total deaths registered, 32 to mesenteric disease, 29 to hydrocephalus, 14 to scrofula, 42 to cancer, &c.

Fifty-two deaths were accidental and 2 suicidal.

Provincial Towns.—Of the total deaths registered in Belfast during the quarter, 196, representing an annual death-rate of 4·3 per 1000 of the population in 1871, were caused by the 7 principal zymotic diseases. Of the foregoing, 62 were caused by scarlet fever, 4 by small-pox, 49 by diarrhœa, 34 by fever, 23 by measles, 14 by diphtheria, and 10 by whooping-cough.

One hundred and thirty-five of the deaths registered in Cork were caused by the 7 principal zymotic diseases, viz., 47 by scarlet fever, 24 by measles, 23 by diarrhœa, 20 each by fever and whooping-cough, and 1 by diphtheria. These deaths equal an annual rate of 5·9 per 1000 of the population.

In Derry the 7 zymotic diseases caused 57 deaths, a number corresponding to an annual death-rate of 7·4 per 1000 of the inhabitants. Of the 57 deaths 41 were caused by scarlet fever, being more than one-fifth of the total deaths registered.

REPORT OF THE INSPECTORS ON THE LUNATIC ASYLUMS IN IRELAND.

A marked difference exists in regard to the respective inmates both in asylums and poorhouses, the number being lowest, or nearly 1·50 in the districts of Down, Armagh, Galway, whereas in Dublin, Louth, Waterford, &c., &c., it is 2·50, and in Limerick fully 3 per 1000, exclusive of the reputed insane out of doors. From the carefully compiled returns of the Commissioners in England it would appear that the insane aggregate under their immediate supervision in 1864 was 44·795, the then population being 20,500,000; with an increase of only 3,060,000 inhabitants, the lunatic element had advanced in the course of ten years by 15,998 patients to 63·973 throughout the kingdom at large, 42·529 being in public asylums, of whom only 2,431 are represented curable. A very important subject for consideration is involved in these data affecting both countries alike, namely, how far the machinery as it were of regularly organised asylums is required for individuals who afford no reasonable hope of recovery. Doubtless there are many inmates of these institutions who under proper local care and proper supervision might with safety be more economically treated elsewhere, but in the great majority of cases the reverse holds good—seven to eight per cent. constituting so far as our inquiries extend, the exceptional maximum, for it must be conceded that within the precincts of an asylum and under trained attendants, some are amenable and quiet, who without judicious treatment would become intractable and dangerous.

With respect to the accommodation in Irish district asylums, not simply meaning the numbers they are made to contain, it is much below requirements, as we have at present almost a thousand in them beyond their legitimate complement. Some are overcrowded by nearly a third, as those at Limerick, Armagh, and Londonderry—others less so. Taking a broad practical view of the subject, all these limited institutions should not only be restored to a normal condition by additions, but supplemented when necessary, so as to meet local requirements, thereby effecting a complete provision for probably 8,200 beds, the existing but imperfect one being restricted to 7,347.

The liberal rate in aid bestowed by Government on the public asylums of the three kingdoms, while protected on the one hand by a considerate economy, confining its expenditure to proper objects, ought at the same time be dispensed by local authorities with an increased regard to the comforts of the insane, for the better maintenance of each thousand of whom the State annually contributes £10,400.

With reference to the general working of district asylums during the past year, we are enabled to report in favourable terms, if their utility as great public institutions is to be estimated by results, embraced within recoveries, improvements, a diminished mortality, immunity from accidents, smaller current outlay, and last, though not least, their moral as well as fiscal management.

The total of both sexes under treatment during the twelvemonth was 9,501, including 2,154 admissions. The actual recoveries amounted to 932, the discharged improved or convalescent to 244, and the deaths to 623. Calculated on admissions the cures reach 43·40 per cent. if on all resident 9·80; while cures and improvements combined are equal to 53·20 per cent. in the former, and 12·5 in the latter contingency. With regard to deaths, the mortatity—particularly if the severity of a long winter and the liability of the insane to pulmonary affections be considered—may be regarded as particularly low, when not exceeding 6·80 per cent., the averape in lunatic institutions generally being 8·40. Included within the deaths are 4 from suicide, and 5 succeeding on accidents in an aggregate daily population of 7,254 patients, of whom in the year 1,174 were received on magisterial warrants and by depositions as evincing dangerous tendencies.

We haue adverted to the moral management of district asylums as exhibited in the conduct and demeanour of the staffs attached to them, which may be stated as uniformly good, and in the opinion of their superior officers satisfactory. Occasionally infractions of duty may have occurred, ending, if repeated, in suspensions, the infliction of fines, or even dismissals, from insobriety, but nothing of cruelty or criminal impropriety, save in two instances when legal proceedings were had recourse to and with success.

The total expenditure, all items of outlay included, on the current maintenance of district asylums in the year 1874 amounted to £184,749, and although there were 240 inmates more in these institutions for the time being, the charges were less by £4060 than in 1873, being at the rate of £25.2 per head, as against £26.4 in the last named year. On the 1st January, 1874, district asylum accounts stood as follows—there was an available balance in hands of £19,078 9s. 1d.; subsequently, and in the course of the year, £184,749 9s. 5d., repayable by grand jury presentments, was received from the Treasury, £2,720 from pay-patients, &2,621 8s. 10d. for farm and garden produce, and £1,353 7s. 5d. from various miscellaneous sources, constituting a total of £216,565 1s. 6d., deducted from which the expenditure as just given for the same period, there remained £20,053 6s. 4d. in bank to the credit of the different boards of governors on the 31st December. The capitation cost varies in different asylums; we find, as a rule, in consequence of repairs, refitments, and minor alterations to meet contingent wants, that the less perfect in construction and worse furnished the establishment at large, the dearer is after maintenance. Having by statute and Privy Council rules so much to do with the direct control and management of district asylums in regard to domsstic details as well as the issue and outlay of money, it is gratifying to us to state that, up to the present, the reports of the Government auditors, who are particularly minute in their inquiries, may be deemed,

on the whole, most favourable. Trivial disbursements, though fully equitable in themselves, have now and then been made by local boards not in strict accordance with regulations, but specially noted at the period of audit, and reported to the inspectors; finally, however, not disallowed, save in some rare instances, the total not exceeding a few pounds.

Re-adverting to patients who after admittance into these lunatic institutions under the 21st Privy Council, and on sanction of the inspectors, they numbered 167 during the year, at an average charge each of £16 17s. 6d. For their support the rate in aid is not available.

Connected with the question of expenditure, there is a matter worthy of remark, viz., the reproductive industry of the inmates of public asylums. On the first establishment of these institutions, nine in number, by a special board of commissioners constituted under the 1st & 2nd Geo. IV., cap. 33, the quantity of land attached to them in the aggregate was only 120 acres, a very limited allowance indeed, in a country where in the absence of manufactures means for agricultural employment ought to have been fairly provided. Since our appointment to office, and particularly after being nominated in 1858 joint commissioners of control, satisfied as to the expediency of having large farms connected with these institutions, we do not fail to urge personally at boards and in our reports of inspection the advantages derivable from increasing the extent of those that appear to us too limited.

In former reports we adverted to the inconsiderate manner, to use a mild term, in which magistrates committed lunatics to asylums as dangerous, in many instances not taking the trouble to make proper inquiry into the merits of the case, in others acting without a due regard to the provisions of the statutes, clear and definite in themselves; thus they injudiciously supersede the functions of the governors of asylums, entail occasionally an uncalled for county expenditure, and give a continued trouble to the executive, obliged for law sake to rectify their errors, in fact to keep them out of harm's way, and a liability to civil actions for illegal confinements of the subject. The evil is certainly being abated through the intervention of circulars to justices directly from Government with a strict injunction to committing magistrates to secure to the reputed insane transferred by them to asylum under warrant, every care and attention during their conveyance, instances having occurred of females being sent from forty to fifty miles alone and under armed escort, and of men being manacled by locks and tied with ropes in the conveyance.

On analysing the summaries of the registered and unregistered insane as already afforded, it appears that at the close of the year 1874 there were 177 less at large of the mentally affected than at its commencement, when they numbered 6,941.

Bearing in view the facilities already adverted to of sending patients to district asylums, it is but reasonable to infer that the types of mental disease in the unregistered as a rule is not of a marked or acute character.

The admissions for the year contained 215 individuals aged from 60 to 78—217 from 50 to 60—321 from 40 to 50—569 from 30 to 40—643 from 20 to 30, and 188 under 20. The largest number in any decades being in the intervals of 20 and 40, when 1,212 were admitted. The insane transferred directly from poorhouses to asylums within the period constituted an aggregate in the proportion of about six per cent. on the total of all classes of idiots, epileptics, imbeciles, and lunatics, which they contain.

A reference to the above statistics of admission bears practically on the past and future, when it is remembered that at the commencement of 1874 there were between the assumed insane at large and those in union workhouses 9,845—2,154 being admitted into district asylums (including three from the criminal asylum whose period of confinement had ceased) 23 per cent. only of the 9,845 may be regarded as during the twelvemonth to have needed special treatment or supervision—while of the 2,154 no less than 1,100 were committed as dangerous by justices, under 30 and 31 Victoria; some little beyond childhood, others in the last stages of debility or senility, who barely reached their destination in time for death.

FOR AND AGAINST ANIMAL VACCINATION. (a)

By Charles R. Drysdale, M.D., M.R.C.P. Lond., F.R.C.S. Eng.,

Senior Physician to the Metropolitan Free Hospital; Physician to the North London Consumption Hospital; and Consulting Physician to the Farringdon General Dispensary.

Continued.

Dr. Jeanty, writing from Virton, in June, 1871, says: "As to vaccinations operated on children, as a general rule we always succeed. Dr. Schener, of Spa, speaks to the same effect. Dr. Verbrucken, of Mells (le Gand), tried and succeeded twenty times with twenty supplies; and Dr. Warlomont mentioned on November 5, 1871, that these vaccinations and revaccinations, operated by more than thirty-six of the most active medical practitioners of Belgium by means of ivory points delivered by the Institute, had given results which surpassed those ever procured by human vaccine lymph, however it might be preserved. For instance, in vaccinations, out of a total of 324 cases there were 303 successes, or 93·5 per cent.; whilst in revaccinations, out of a total of 5,425 cases there had been 3,419 successes, or 63·2 per cent—a figure higher than that of revaccinations operated by arm to arm vaccination, as shown by statistics. He, therefore, concludes—1, that animal vaccine lymph dried on ivory points, such as is delivered by the State Vaccinal Institute, is in no ways inferior in revaccinations to human vaccine lymph taken from arm to arm, nor in vaccinations to the same vaccine lymph preserved either in tubes or between glass plates. It is infinitely superior to liquid animal vaccine lymph preserved by the processes hitherto made use of. 2. It gives to persons on whom its inoculation has failed, and who judge it useless to submit to a new operation, the same security that any other species of vaccination could yield, even that from arm to arm."

In pages 9, 11, 12, 13, 14, and 20 of his classical work, referring to Cases 1, 2, 3, 4, 5, and 8, the last of which cases was inoculated thirty-eight years before, Edward Jenner, writing in 1798, asserted that any farm labourer who had at any period of his life had cow-pox was after that sheltered from the small-pox. Of course we now know that *human* vaccine does not completely carry out that ideal of excellence; but does it still hold good for cow-pox? Of this I presume that out of Italy no European nation has as yet any sufficient evidence. Dr. Warlomont seems to have some notion that animal vaccination is a better safeguard against small-pox than human vaccination. He says: "I don't know what my colleagues have observed; but, for myself, I declare I have yet to wait for a single one of my successfully vaccinated or revaccinated cases (and they have amounted to over 10,000 in the last five years) which the demon of small-pox has been able to attack."

He also quotes Dr. Roels, who, writing in June, 1871 says: "A singular fact, and one I think it a duty to report to you, has occurred to me during this epidemic. The commune of Gouzy le Pieton, where I live, is next to that of Trazegnies and Courcelles (Hainault). The disease has reigned at the same time and with virulence in the three communes. At Trazegnies and Courcelles many very young children, regularly vaccinated, were attacked by it and succumbed. But at Gouzy le Pieton there was not one case of small-pox among the vaccinated children younger than five years. This fact struck me, and I communicated it to my honourable friend, bourgmestre M. Delgouffre, who had made the same remark. I declared to him that in my eyes this beneficent influence, which was so mysterious in protecting our little children, was none other than animal vaccination."

It has been said that animal vaccine causes greater local disturbance than human; but Dr. Warlomont assures us that this is quite an unfounded charge. In France animal

(a) Read at the Medical Society of London on the 15th November, 1875. Dr. Routh, President, in the chair.

vaccination does not make the way it might be expected, owing chiefly to the use of tubes for preserving the lymph, which process is quite contrary to all Belgian rules, and must be abandoned if animal vaccination is used.

Non-Identity of Variola and Vaccinia.—The illustrious Jenner, struck by the preservative properties of vaccinia, in common with other physicians subsequently, and especially Ceely and Thiele, thought that small-pox and vaccinia were but the same disease. It appears, however, that the experiments of Chauveau, of Lyons, assisted by Viennois and Meynet, have proved that small-pox is inoculable on the cow; but that the organism of the bovine species is but little suited to reproduce this virus, so that it remains there in a condition of merely local eruption, so as not to be capable of being reinoculated on a fresh subject. Nevertheless the cow, when inoculated with variolous matter, loses the power of contracting the vaccine disease. Hence variola and vaccinia do not pass into each other, as has been surmised.

"In vaccine lymph," says Chauveau, "there is, on the one hand, the serosity, containing the albumen and other soluble substances; and, on the other hand, the solid elements—that is, the leucocytes and elementary granulations, kept in suspension in the serosity. By utilising the well-known phenomena of diffusion we recognise that the vaccine serosity in cow-pox, absolutely deprived of all its solid corpuscles, and the finest granulations, is deprived of virulence, and thus the activity of the vaccine resides in the solid granulations, either indistinctly in all of them, or only in a part of these minute elementary organs. This is the reason why cow-pox cannot be kept for any time in tubes. The solid portion so quickly separates from the serum that it is impossible to keep the lymph homogeneous for more than a few hours."

The following is the text of the printed circular sent out with the ivory points from the Brussels Institute:—

"Institut Vaccinal de l'Etat, Direction, 74 Avenue de la Toison d'Or.—Royal Decree of July 14, 1868 (*Moniteur* of the 14th July), Extract, Article 5.—The gratis distribution of vaccine lymph is limited to two tubes or points a year for each practitioner. The director shall, however, be called on to satisfy all demands made upon him, but may require from the administrations of each commune a payment of one franc, and from private practitioners two francs, for each piece exceeding the above limit. He is, furthermore, authorised to deliver vaccine to private persons at the rate of two francs each point. The Direction also authorises practitioners, especially those in country parishes, to ask for gratis vaccine whenever they are in want of it to renew their stock, to the profit of the public health, stating in the letter whether the demand is the first made in the year or supplementary.

"Practitioners of medicine and communal administrations, in places where there are no physicians, have alone the right to obtain vaccine gratis. They must make a written demand for it, by prepaid letter, to the above address, accompanied by a stamp of 10c. to prepay the return letter. For each supplementary point they must add, for the first, two francs, and for the others, one franc per point, in a post-office order, or by stamps of 10c.

"HOW TO USE THE POINTS.

"Plunge the point quickly into tepid water, and after its withdrawal, leave the vaccine to soften for two or three minutes. Make three scratches at 1mm. distant from each other, and of some 4mm. long, only cutting through the epidermis, or one circular scratch by means of the vaccination trephine. Should a little blood flow, allow it to dry; then pass over the part when it is dry the vaccine point several times. Rub in the lymph until the point is free from vaccine; should blood mingle with the lymph collect it on the incisions, and let it dry there. One point should not be considered sufficient for more than one vaccination."

NOTE.—In order to distinguish the ivory points used for animal vaccination from those used for human lymph, they have been made much larger, and measure about two inches in length and quarter of an inch in breadth.

It is, perhaps at this point that I ought to mention what has been said for and against vaccino-syphilitic contagion. In the year 1800, Mosely (*A Treatise on Cow-pox*, 1805) asserted that cases which would seem like syphilis, appeared after the vaccination of some children. In 1814 Monteggra, of Milan, read a paper recognising vaccino-syphilis. Marcolini, in 1823, published a memoir (*Ann. Univ. d. Med. Comp. da Annib. Asmodes*), where he mentions having noticed in 1814 the transmission of the two viruses. In 1821 and 1824 Professor Cerioli, of Cremona, related cases where syphilis had been spread by vaccination. In 1831, Dr. Bidart, of Pas (Pas de Calais) (*J. de Med. et d. Chir. Prat.*, 1831) alleged that the disease could not be communicated by vaccination. In 1839 (same journal, 1839, t. x.) the Société de Médecine of Paris debated this question, and resolved it in the negative. In 1842 Dr. Sigmund, of Vienna, asserted that chancrous pus destroyed vaccine lymph, when both were inoculated together. He probably used the pus of soft chancre. These experiments were published at the trial of Dr. Hubner, in Prussia (*Erfah ub. Vac. Syph. Krank. mit Ruck. auf d. Angeleg: der Gerichtartzis*, Wien., 1855). In 1855, Ceccaldi, of Constantin (*Rev. Med. Chir. de Paris*, 1863, t. xiii.) gave three cases of vaccino-syphilitic contagion. In 1849 Dr. Viani (*Gazz. M. Lomb.*, 1849) gave a case of the same kind. In 1850 an article, signed Wegeler, appeared in the *Med. Zeitung* of Berlin, where nineteen persons were made syphilitic out of twenty-four vaccinated by a veterinary surgeon. In 1855 Sperino and Beaumetz repeated the experiments of Dr. Sigmund, but did not confirm them. In 1855 Dr. See resumed the trial of Hubner (*Gaz. Heb.*, March, '55) where, in 1852, thirteen children were rendered syphilitic by vaccination. In 1854 Dr. Monnell, of New York (*Med. Times and Gaz.*, 1854) published a case. In 1859 Dr. Whitehead, of Manchester, in his third report of the Clinical Hospital of Manchester, mentioned thirty-four cases where children became syphilitic after being vaccinated, some of which seem to have been true cases of vaccino-syphilitic disease. In 1859 Dr. Lecocq (*Gaz. des H.*, Dec., '59) reported two important cases of syphilitic infection of soldiers by means of vaccination. In the debate on vaccino-syphilitic contagion in the Academy of Medicine, in 1864, in Paris, M. Trousseau mentioned some cases; one of which had been seen and lectured on by M. Ricord. Auzias (Turenne) and Bouvier also mentioned cases; but many speakers, including Ricord, were still completely sceptical as to the possibility of its occurrence. Thus some orators mentioned that they had taken the lymph from syphilitic infants and vaccinated with it without producing anything unusual.

In England a general scepticism as to the possibility of the occurrence of vaccino-syphilis has existed until quite recently. Mr. Seaton seems to have shared the general scepticism until lately, when, on June 27, 1871, Mr. Jonathan Hutchinson communicated his two series of cases of vaccino-syphilitic inoculation to the Royal Medical and Chirurgical Society of London. In the first series of his cases, twelve persons, mostly young adults, were vaccinated from a healthy-looking child. The vaccination progressed favourably in all; but indurated sores appeared on the arms of those vaccinated on the 8th week. All of them were treated by mercury, when the primary sores rapidly disappeared. Constitutional symptoms appeared in four of the patients in five months after vaccination. The vaccinifer showed condylomata at the age of six months. In the second series of cases there were signs of constitutional syphilis in nine children, all vaccinated from the same patient, and suspicious symptoms in six others. The vaccinifer was a fine, healthy-looking child, but with slight local symptoms indicative of inherited syphilis.

Hutchinson's series of cases seem to indicate that it is nearly impossible for any ordinary practitioner to be sure that a vaccinifer from which he is about to vaccinate

is thoroughly free from danger, unless, indeed, he strip the infant and examine it most carefully from head to foot. In the latter series of cases just cited there was no mention of blood having been drawn with the lymph. The well-known experiment of Pellizzari, of Florence, who, on February 6, 1862, inoculated successfully syphilis on his friend, Dr. Bargioni, by means of the blood taken from a syphilitic woman, proves the virulence of syphilitic blood; and in this case a hard sore appeared in twenty days. But in some cases of vaccino-syphilitic contagion the inoculation of other products seems to carry the disease with it.

What has hitherto been said tends more or less to the adoption of the process of animal vaccination; but much has been said, and doubtless will be said, against this innovation. Professor Crocq, of Brussels, for instance, in a debate in 1871, professed himself still a disbeliever as to the existence of vaccino-syphilis, observing, in passing, with truth, that syphilis is the only disease clearly attributed to vaccination by medical authors of repute. Nevertheless, he confessed that he would not venture to vaccinate any child from the arm of a syphilitic infant. Crocq, in common with many others, asserts that the preservative powers of vaccine matter are as great now as they have ever been. There is, in short, but one vaccine matter, always identical with itself, and hence never requiring to be regenerated. Regeneration takes place in all viruses when they reach a propitious soil.

(To be continued.)

A CASE OF CHRONIC RHEUMATIC ARTHRITIS OF THE HIP; WITH SOME REMARKS ON THE TREATMENT OF THE DISEASE. (a)

By Henry Kennedy, M.B.,

Physician to the Whitworth Hospital, Drumcondra, and Simpson's Hospital; President of the Pathological Society.

As the following case presented more than one feature of what seems to me to have a practical bearing, I venture to hope it may be thought worthy the notice of the Society I have now the honour of addressing. The disease of which I am about to speak may be described as occupying neutral ground between medicine and surgery; whilst in no city in Europe has its natural history been more thoroughly investigated, or its morbid anatomy described, than in Dublin. My general remarks, however, will probably come in better after I have given the details of the case.

A lady of 45 years of age, of tall stature, sanguineous temperament, and in easy circumstances, began to complain just two years since of some unpleasant feelings referable to the right leg. At first she was quite unable to describe her feelings. She only knew they were not those of health, and the more so as her habits had been of a very active kind. By degrees, however, a feeling of uneasiness, referred to the right hip-joint, attracted her notice, and after any unusual amount of exercise she was conscious of a sense of aching in the whole limb, which, however, went away on going to bed. A few weeks later she observed that certain movements gave her pain. Thus the crossing of one knee over the other became unpleasant to her; as also the act of rising from her knees; and going up and down stairs she could not accomplish as formerly. Finally, in June, 1874, she consulted two medical gentlemen residing in a large town near her. They at once detected the disease of the hip-joint, of the nature of chronic rheumatic arthritis, and advised her to go to Dublin and consult the late Mr. Adams, at the same time saying or implying that little or nothing could be done for her. With this unfavourable impression on her mind she came to town and saw Mr. Adams, who confirmed the diagnosis already made, and advised her to go to Aix-les-Bains, and on her way through London, to see Sir James Paget. This she did, and then proceeded to Aix, where she used the baths and douches most assiduously for six weeks, and then returned to Dublin, but, as she thought herself, without any improvement in her state. In consequence of Mr. Adams' failing health, I was now asked to see her, and did do so in the beginning of December, 1874. I found all the symptoms of the disease well marked, there being, in addition to anything yet stated, distinct wasting of the thigh especially, and also marked coldness of the whole limb; neither could she lie with any comfort on the affected side. The disease had now existed for a period of at least nine months. Having obtained Mr. Adams' concurrence, I resolved to treat the case specifically, and see how far a continuous line of treatment would or could modify such a disease. Acting on this idea, leeches were directed to be applied as close as possible to the joint, and this was done at intervals again and again, and to this was added everything which could in any way conduce to her general health. As a tonic, she got a mixture of which conium in large doses was the chief ingredient. As to exercise, she was allowed to use any which did not cause aching or uneasiness in the limb. After the leeching was given up frictions to the entire limb were very steadily carried out. These measures improved her very much, and by my advice too she now visited Harrogate and Buxton during the past summer. The result of this treatment has been very satisfactory. The patient can scarcely be persuaded but that she is quite well. She is able to take long walks, can go up and down stairs like any one else, and in fact seems well. For myself, however, I would be very slow in pronouncing her cured. The nature of the disease, at least as far as we know it, forbids this idea. I think, however, I am justified in saying that the disease has been stayed in its course, and this is at least something to have gained, and to hope that in the future it may be possible to prevent it getting worse.

As to the causes of the disease in this particular case, it may be mentioned the patient was in the habit of spending hours in gardening, and this she did totally irrespective of the weather, and she frequently remained in damp clothes. Wet has been set down as a leading cause of the affection. That it is a predisposing one may, I think, be granted. Further than this I would not be induced to go.

What is the nature of this disease? Many think it an acute or subacute inflammation. But the late Mr. Colles denied this, saying he never saw lymph or pus in connection with it, and this would seem to be very generally true. It is probably on this very point, however, that its real nature turns, for on the one side it must be admitted that many of the marked effects of the disease bear the direct impress of inflammation. Thus there is swelling, redness, pain, and morbid growths. You, Mr. President, exhibited at one of the earlier meetings of the Pathological Society, this winter, a very striking example of these points, and affecting, too, both hip-joints. We may surely call these appearances inflammatory. Yet, on the other side, Mr. Colles' observation must not be forgotten, for if lymph or pus be ever produced it must be exceedingly rare. Now it is this kind of contradiction, if I may so speak of it, which seems to point out the nature of the affection, which I take to be rheumatic gout, and essentially a constitutional disease. It is curious, however, to observe how frequently the hip is affected alone, though there are exceptions to this, as in the case just alluded to, and in the instance of the late Dr. Perceval, who suffered greatly from the disease in both joints for years before his death. The late Mr. Colles exhibited these specimens before the Pathological Society at the time. There is one other point connected with the morbid effects produced by this disease which is worthy of notice. The bones themselves seem sometimes, in the earlier stage at least, to soften, and, possibly, yield to pressure. In some of the speciments this is observed by the

(a) Communicated to the Surgical Society of Ireland on the January, 1876. The discussion will be found at page 92.

acetabulum yielding towards the pelvis. In treating the disease this is a point not to be overlooked.

From what has just preceded, the treatment which I adopted in the case detailed will be readily understood. Not that it has the slightest pretension to novelty, for all the works which treat of the disease specially speak of leeching. I have reasons however for thinking that this plan is not as generally carried out as it deserves to be, and more particularly the systematic way in which it was done in this case. It was certainly the first means used which had any effect on the disease, and with the other means used, and which have been spoken of, had the effect of bringing about the state in which the patient now is. I take it that the inflammation, of whatever character it may be, has been stopped, at least for the time, and that in the future it may be possible by similar means to keep it at bay. If nothing more than this be gained I believe it to be an important point, for I presume I address few who have not met cases where the suffering, to say nothing of the crippling, has been very great, and the lives of the sufferers rendered miserable by the disease. One word more and I have done. When I first saw the patient, and during the time the leeches were being applied, she was directed to take very little exercise, or at any rate none which was followed by a sense of uneasiness or aching in the limb. From what has preceded, the reason for this advice will be obvious. Now, however, matters are altered, and the amount of daily exercise taken on foot is very considerable, and has my entire approval.

ON GERMS. (a)

By Professor Tyndall.

The object of this lecture was the same as that of Prof. Tyndall's paper before the Royal Society on Thursday week. While in it, however, he merely laid the result of his experiments before the meeting, on this occasion he endeavoured to point out some of its possible practical bearings when viewed in relation to medical science. The basis of Professor Tyndall's experiments is that, in the course of searching for means of obtaining air free from floating motes, he found that if air is allowed to remain in a closed air-tight vessel covered inside with glycerine, in the course of three or four days it deposits all its motes which adhere to the glycerine, and it thus becomes quite free from them. The test of its perfect freedom is to pass a powerful beam of light through the case, when, if any motes are still floating, they make known their presence by reflecting the light. With air thus purified, Professor Tyndall has made a long series of experiments bearing on the question of spontaneous generation and on disease germs. He has placed test tubes in cases like those referred to, and has arranged to fill the tubes by a pipette so arranged that it can reach the tubes without admitting external air. The method is to allow the air to settle and purify itself, and then to pour in the infusion down the pipette. At the same time a portion of the infusion is placed in tubes exposed to the ordinary air. The usual precautions and preparations laid down by those who believe in spontaneous generation are carefully observed. Thus, one sample of an infusion is exposed to the influence of motes, and another sample is protected from them. Over and over again with different kinds of infusions the experiments have been tried. The protected tubes show no change, while the exposed tubes soon become putrid and show signs of low forms of life. Now, though we know nothing about motes of the air, yet the Professor puts it that it is fair to argue thus:—Suppose these motes were so large that we could handle them. If we took two pots of earth, planted some of the motes in one, and carefully kept them from the other, and if we got a crop of cresses and grass from the first and nothing from the second, we should surely argue that the motes contained the germs of this vegetation. So with these minute motes and the infusions which favour their development. We allow them to settle in one set of infusions and get a crowd of life forms; we carefully keep them away from another set of infusions and get no life. Surely the minute motes contain the germs among them. In various ways, with sealed flasks, with calcined air, with filtered air and *in vacus* experiments all tending to the same results were exhibited. Some of the failures in experimenting were referred to, and it was seen how easy it is to be misled into accepting apparent proof of spontaneous generation. In one instance a tube in one of the cases spilt a few drops of the infusion. It fell on some germs lying on the glycerine, and, furnishing to them a means of development, life forms were soon seen and a putrefaction on the spot set up. The case being near a stove, which heated it on one side, currents of air were produced within it, and some of the germs got wafted into one of the tubes and set up putrefaction and forms of life in it. Yet, although this went on for some time, and the evaporation from it was all round the other tubes in the same case, they were not affected. Directly, however, a drop from the putrefying tube was transferred to one of the others, it set up a series of changes at once. From this Professor Tyndall argues that sewer gas of itself is harmless; it is the germs floating in the sewer gas that sow disease. If there are no disease germs present, the gas does no harm. Another set of experiments on the horizontal and vertical distribution of motes led to the conclusion that life-germs float in little clouds, since an immense number of tubes exposed in different parts and at different heights in the laboratory showed that some were affected many days before others. Clouds of disease germs may explain a puzzle to surgeons—why a wound going on well for a while should suddenly, and without apparent reason, become putrid. It may be that it is being dressed just at a time when a "germ cloud" is passing. In his concluding remarks, Professor Tyndall referred to the fact that it has remained for modern science to discover that, more than by battle, or accident, or famine, humanity suffers from disease germs conveyed in air and water.

(a) Abstract of a lecture delivered at the Royal Institution.

ON CLEFT PALATE.

By E. A. Rawson, M.B., M.Ch., &c.

Finding the usual means for approximating the edges of a cleft palate tedious, to say nothing of their difficulty, I have devised a litte instrument which I believe will facilitate the operation very much. It was made for me by Weiss some months ago, and since then I have not had the good fortune of a case to try it on. I therefore venture to suggest my plan to the profession in general, and trust that any one approving of it will try it and publish the result. The instrument is simply a safety-pin, or rather needle, used on the same principle as that for fastening children's clothes.

It is about three-quarters of an inch long and slightly curved: at its head is a flat silver knob, to which is attached a spiral silver spring; this spring is shorter than the needle, and on stretching it a sheath at its free extremity receives the point of the needle.

The edges of the cleft having been pared, the needle is passed in through one and out through the other, giving a good grip to secure apposition, and going nearly or quite through to the back; the silver sheath fastened to the spiral spring is then drawn across and receives the point of the needle, thus retaining the latter in its place. Two, or as many more needles as are required, can be applied, and when union is complete, can be withdrawn by pulling the sheath from the point of the needle and taking the latter out in the usual manner.

Of course all this must be done by means of handy forceps.

The pared edges of the cleft might also be held in appo-

sition until union had taken place by means of a small trout-hook, fastened to each end of a spiral silver spring half-an-inch long; "india-rubber, I fear, would soften;" one hook held in a forceps to be plunged into one lip of the cleft, the other hook to be then seized and drawn across, extending the spring, and secured in the opposite lip; the barbs, I think, might be left on the hooks, as they would make certain of retaining them in their places, and every angler knows how to withdraw a *small* barbed hook —viz., by making a slight nick in the flesh at the back of the barb, pressing the hook slightly onwards, then outwards into the nick, when it will easily withdraw. This experiment can be tried on a piece of cloth.

Or, instead of a spiral spring, the hooks might be fastened to a piece of silver wire, which, when they were applied, could be twisted until the pared edges were in apposition.

I would recommend the very smallest trout-hooks, as larger ones might pierce through into the posterior nares, and when the soft palate was raised seize the opposite lining membrane. I can see an objection to the hooks, for in using them the back of the wound would not be in such close approximation as the front, but they would be much easier of application than the safety-needle, which, however, has the advantage that it would retain both back and front of the wound in perfect apposition.

In one case, that of a child, 2½ years old, in which half an-inch of the bony palate was cleft, I used the actual cautery as above, afterwards stitching with three wire sutures, which, however, all gave way. Some time afterwards I received a letter from the mother to say that the cleft had healed, leaving a white seam in its place, and that the child could speak quite plainly. I went to see it, and found the cleft *partially* healed and the remaining part in such close approximation as to deceive a superficial observer.

Vesico-vaginal fistulæ and such like deep and difficultly situated lesions might be found easier of treatment by the foregoing.

ON THE CAUSES OF EPIDEMICS.

By T. Baker, LL.B.

Sir Wm. Jenner, President of the Clinical Society, asks "What are the conditions which favour outbreaks of epidemics?" (*Lancet*, 25 Feb., 1875), and he urges upon observers the importance of reporting all such facts as may tend to throw light upon the inquiry. Are all specific diseases contagious? *i. e.*, "from some part of the sick is something given off which can, when properly applied, excite the same disease in another, and which can excite no other disease?" "How little," he remarks, "is known of what that something is!"

In considering this subject we ought first to settle what is to be received as evidence: 1, of this "giving off;" 2, its proper application; 3, its reception or absorption by others. Mere assumptions have sometimes heretofore been called medical evidences. "In consequence (as I must suppose) of a breach of quarantine regulations, which, however, could not be detected, a family belonging to the dockyard was attacked with the disease," wrote a superintendent of quarantine. And a certain statistician writes, "It is estimated" so and so; "so that if we can assume" so and so; "it will follow" so and so. And this has been accepted as evidence that the consequence indicated *must* follow! But can such reasoning be admitted by any scientific body of men?

Before decisively attributing the communication of disease to contagion from person to person, is coincidence to be deemed possible? Or that exposure to like causes may produce similar effects? And is the previous state of those thus said to be infected to be taken into account?

A child convalescent after measles arrives among a family of 16, and "one only takes the disease." Another having the disease comes from school amongst 8 others, only two of whom suffer, all being freely exposed to the poison.

Seven out of 10 young men contract typhoid fever in the same house, without communicating the disease to anyone on returning to their respective homes. One, out of several clinical students, sees a case of small-pox in a large hospital ward, and takes small-pox.

An obstetric practitioner, having several cases of puerpural fever, believes that he had communicated the fever from one to another by his hands; these either not having been sufficiently disaffected, or, as another suggests, through the perspiration of moist hands.

Enteric fever breaks out in Marylebone, and it is reported that milk from a particular farm, having been supplied to that neighbourhood, must (though many escaped) have conveyed the poison through well water impregnated by soakage from piggeries, &c., having been drunk by the cows and mixed with the milk.

Sir Wm. Jenner points out the effect of constitutional proclivity to particular diseases; also that too little importance is attributed to bodily condition, or "out-of-healthedness," arising from erroneous habits of living. He further dwells upon the production of typhoid by imbibing excreta in water used for drinking purposes.

The object of this paper is not to dogmatise, but simply to suggest investigation. Nothing perhaps is more easy than to be led into fallacy in the consideration of evidence as to the communication of disease; especially if the investigator has any preconceived ideas on the subject.

Taking the cases above-mentioned in their order: It is so common for children to have measles, that most people consider it essential to the child's welfare that an attack should be suffered. May not the arrival of a convalescent among the 16, one of whom got measles, be a coincidence merely? Might it not be that bacon or pork in an unsound state, or pastry made with lard, may have been consumed by each patient nearly at the same time? and that the tendency about the period and neighbourhood, in each case towards any exanthematous disease, whether an epidemic prevailed or not, was towards measles? Ere accepting bodily contagion as the all-sufficient cause of measles, or any other eruption, would it be well to inquire carefully into all the dietetic habits, the local surroundings, and the physiological condition of the patient in every instance?

Why may not measles be sometimes inoculated by the ointment applied to wounds? A vast deal of ointment is sent about the world, and lard probably forms the foundation of most of it. Excess of fat is disease in any animal; measles is peculiarly the swine disease; hogs are grossly fatted before being killed (to save their lives); and this most unwholesome part of their carcase is melted down for town-made butter, confectioner's or domestic pastry, and ointment by whomsoever manufactured. Might not the microscope be here usefully applied?

The seven young men who contracted typhoid while located in one house probably each returned to a healthy home, properly ventilated, free from local impurity, and where the diet would be exempt from some probable irregularities practised in the infected house.

The fever wards of our London hospitals claim, of late years at least, to be well ventilated, and it is generally admitted that under such conditions fever does not spread. There was perhaps therefore nothing remarkable in the clinical students escaping typhus; and as it seems only on one occasion that one alone out of several suffered an attack of small-pox, after seeing a patient in the wards, is it quite impossible that some other conditions, such as "out-of-healthedness," of this student, poison in some other locality he had visited or lived in, &c., might have been coincident with his visit to the hospital?

Much has been said upon the conveyance of disease by drinking water, as well as "germs" through other sources, bacteria, &c. Has each investigator been careful to inquire whether or not the person attacked in the house supplied with impure water was in the habit of drinking water at all? Intemperance is one of the most prolific causes of fever; and it is by no means uncommon for intemperate persons to deride the very notion of ever tasting water. Like the Hollander—

"Of water alone he drinks no more
Than a rose supplies
When a dew-drop lies
On its bed in a summer morning."

Again, if cooking or tea be pointed at, may it not be useful to investigate what effect in the purification of noxious matter held in aqueous solution is produced by boiling such solution?

With reference to enteric fever from milk, it is well known that any poison taken into the animal system will be cast out by dame Nature by the readiest available method. Hence, during lactation, any impurity imbibed by the mother may, by killing the infant, be prevented from injuring herself. So if these cows really absorbed water proved, by chemical analysis, to contain sufficient foul soakage to have diseased the animals themselves had they not been giving milk at the time, such milk would undoubtedly be unwholesome. Perhaps it was found that other animals on this farm, drinking the same water, *e. g.*, bulls, heifers, pigs, sheep, &c., *were* all more or less diseased?

But if soakage through a considerable quantity of earth from so small a surface is capable, indirectly, of causing so much mischief, what epidemics might not be ascribed to the over-manuring of large tracts of highly-farmed land in moist, open, calm seasons, by impregnating the air of neighbouring districts to leeward?

Was it satisfactorily shown that in no case could either the local surroundings in Marylebone, or any habits of the patients, unsound food, or other cause, have induced this outbreak?

In considering the causes of puerperal fever most especially, should not the peculiar state of the patient be taken into the account? Both strength and endurance then are sorely tried. The nervous reaction—as Dr. Richardson has well observed—must be immense by the stoppage (almost equivalent to the loss of a limb) of one kind of nutrient process through the blood, and the commencement of another in lactation. We surely have here a concatenation sufficient to produce the keenest susceptibility to any added cause or poison. What were the habits of the unfortunate obstetrician in regard to ventilation? Did the unlucky nurse allow her patients to poison themselves, aided by their attendants, from the dread of an open window? Of all aids to cholera, the defunct General Board of Health found want of ventilation, or lung poisoning, the most pernicious. Again, in each case should we not ask what was the physiological condition of the patient's blood? Was it such as to be highly inflamed by a scratch or rupture? Had it been receiving nourishment from sheep-pox mutton, from measly pork, vitriol gin, cocculus porter, or sewer-water tea (if boiling does not destroy that evil)? Was there any hereditary disease or tendency, &c., &c.? Should not all these questions be sifted thoroughly before a medical practitioner accuses the moisture from his hands?

It is well known that in warm climates yellow fever patients have been frequently nursed with impunity, when taken out of the focus of infection, and conveyed to neighbouring high lands. People were often much influenced by fear of contagion, however; so much so, that when at Rio de Janeiro in 1849, the Russian ambassador visited the yellow fever hospitals, the British Consul was compelled to report that "that distinguished man found none to imitate his example." Yet there was no hint of his having caught the disease.

(*To be continued.*)

Clinical Records.

ST. MARY'S HOSPITAL, LONDON.

Farcy—Death.

Under the care of Dr. BROADBENT.

(Reported by Mr. SWORDER.)

ELIZABETH CUMMINGS, æt. 18, servant, admitted Feb. 25th, 1874. She stated that she was taken 14 days previously with pain in the upper part of her right leg. The skin was at first of a natural colour, but in a day or two a large red patch appeared over the right knee, which was from the first exquisitely painful. Her father was a horse-keeper, and the patient lived over the stables. One horse was believed to be suffering from glanders. When first seen she was unable te move in the least in consequence of the pain in right knee. The upper part of the right leg was swollen, and upon this part was a large red patch, suggestive of erythema nodosum. Temperature, 104·2°; pulse, 140. A prolonged first sound heard over apex, and at xyphoid; tongue red and dry. The patient could sleep but little, on account of the pain.

On the 26th the corresponding part of left leg was swollen and painful. There was also a red patch 1½ inches square below the knee. Temperature, 104·2°; pulse, 132.

On the 27th the temp. 103·6°; pulse, 120. Red patch on left leg rather larger. The right knee-joint contained fluid. There were also pustules on the face and on different parts of the body, and the patient had been delirious.

On the 28th the temp. and pulse were the same as on the previous day; urine, acid; specific gravity, 1018; no albumen. There were a few isolated pustular spots down the right arm, and on the neck and legs; lids of left eye swollen; two patches of confluent pustules above the inner canthus and eyebrow; a large patch of redness on left elbow, with a few pustules in the centre.

On the 1st March the temp. was 103°, and the pulse rose to 130; respirations 36, shallow.

On the 2nd the pustules on the face increased in number; patient was delirious all night, and also at times during the day; both eyes were stopped up with œdema; she lay with her mouth open; breathing was slightly stertorous; she swallowed with difficulty; the red patch on left leg was much larger; the left hand puffy; temp. 104°; pulse, 148; respirations, 36

On the 3rd she was sensible at times only; moaning occasionally; more pustules on face and body; the mouth wide open. There was a slight discharge from right nostril, and also from the eyes; urine and motions passed involuntarily. The red patch on left knee was larger, and there were two or three bullæ over it; on the right leg was a large swelling, extending half-way down the leg from the knee; the veins were dilated; cellular suppuration was commencing; temp. 102·2°; pulse, 144; respirations, 36.

On March 4th she swallowed with great difficulty, and took but little nourishment. Her face was covered with pustules, some of which were confluent; the right nostril was stopped up, and there was a foul discharge trickling down over the lips; both eyelids were closed up, were reddened and œdematous, and discharged pus; tongue raw; lips and teeth covered with sordes. She died at 12.45 p.m.

Post-Mortem Appearances.—There were some adhesions of pleura, with slight recent inflammation; lungs were knotty and hard in parts, and on being cut into were found much congested and œdematous; the hard masses were circumscribed abscesses containing curdy pus, the lungs being riddled with them. The bronchial glands were much enlarged, but healthy; heart normal; pale brownish-white clot in right auricle and ventricle extending into the vessels. Peritoneum slightly inflamed; liver congested, fatty, but no abscesses in it or purulent deposit. Kidneys: left, large; capsule adherent, somewhat fibrous. Right, very small; capsule adherent. Both were congested. On

making an incision into the right calf a quantity of pus escaped.

INDIAN MEDICAL NOTES.—XLIX.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE DIVINE HILLS—ELECTRICITY—NITRITE OF AMYL.

In spite of rains delayed, the month of July was so healthy at Meerut that very reluctantly a few days' leave were solicited. Running away has many objections, is very expensive, but the only remedy for certain ailments. On again, therefore, by rail to Saharunpore, celebrated for botanical gardens and the Government stud establishment; on from there a weary drive to the Sewaliks, or first range of hills; then through a lovely pass piercing the lofty wooded peaks and rugged precipitous crags; the road through beds of mountain torrents, sometimes bridged, else over stones and boulders, then through a tunnel, and eventually, after a fair amount of bumping and jolting, the travellers approached the Deyrah Doon, a beautiful valley between the true Himalayas and the Sewaliks, about 60 miles long and 14 broad, placed between the Ganges and the Jumna. By some considered the bed of an ancient lake or small inland sea, this valley of alluvial soil produces wondrous varied vegetation, including roses, sweet-briars, violets, the fragrant corunda, plants, flowers, and vegetables without end; and the graceful, stately bamboos often unite into exquisite arches, constituting lordly avenues up to the comfortable houses of the few scattered Europeans. Shut in between mountains and bounded by the two rivers, it stands to reason that, mild as the climate is, at one time the vegetation, the want of air perflation must at certain seasons conduce to fever, especially when natives pollute the drinking water, which rapidly was flowing through open brick channels into Deyrah. We hurried through the bazar where the little black Goorkhas riflemen loitered, and at Rajpore, the foot of the Himalayas, quitted the omnibus. Slowly crawled the sure-footed ponies, zig-zag, scrambling six miles up the narrow mountain path through pelting, pitiless rain, and, thoroughly drenched and wet to the skin, eventually we reached the Himalaya Hotel. Mussooree and Landour have been mentioned before; suffice it now to tell of the trunks and branches of glorious trees being covered with soft, velvety, emerald moss, from whence varied ferns with fronds of exquisite tracery sprung; of the white and pale blue striped with pink convolvuli clinging elsewhere; of the wild dahlias, monopetalous, with golden centres, either mauve, magenta, purple, crimson, damask, orange, red and white striped, primrose—a bright blaze of colour on the green hill slopes, where the humble heliotrope and the lilac-coloured iris modestly peeped out or nestled amidst the sturdy blades of grass. In the well-trimmed gardens will be noticed the non-indigenous cultivated dahlias, pretty fragrant roses, geraniums—single and double; also elegant fuchsias with centres of every colour; no rhododendra or any other trees were in flower. Above 7,000 feet, besides oaks with prickly leaves and enormous acorns, grow, according to report, the sycamore, box, yew, filbert, and morenda pines. Cedars flourish at a great height. Above 13,000 feet the trees cease, and, amid the silence of the snows, grow grasses, herbs, and mosses only. At certain seasons variegated cowslips, sweet hyacinths, and rare orchids are noticed at Landour, where the soldier invalids do so well, especially the boys. My greatest pleasure this year was to stroll with a lad who, for months, at Meerut, had hovered between life and death, for some time delirious, next afflicted with pyæmia, and bed-sore after bed-sore, about thirty in all; then both eyes were in jeopardy through ulceration of the cornea. Yet, thanks to Landour and a good constitution, here he was to-day talking of returning to duty soon at Delhi. At some hill stations lurks at times a tendency to puerperal fever or erysipelas; at others, to measles or croup; at others, again, either to neuralgia, diarrhœa, dysentery, hepatitis, or rheumatism; but Landour, almost perfect, is highly recommend for children; so is Darjeeling, 7,161 feet, with a rainfall of 10 feet between June and October, where the children bloom marvellously, and do not catch cold when taken out in the drenching showers. At the Lovetto Convent one child only died in twenty years. At Murree, 6,500 feet, out of 85 children a year, but 6 deaths in 10 years; at Mount Aboo, 4,500 feet, out of 50 children 1 death, that an epileptic, in 5 years. As pointed out before, the Himalayan air tries the feeble heart. One afternoon a smart-looking Hussar rode past the Hotel along the Mall apparently in good health, and in about two hours his body was carried past the same spot, for he suddenly died, as people die anywhere, of obscure cardiac disease. One morning I was suddenly summoned to an invalid married lady, under 30, several years in India, with a history of fainting, attacks of fever, and exhausting diarrhœa; after a restless, miserable night, the latter ailment aggravated, there was great debility, abdominal pain, and an urgent cry for relief. The regular medical attendant, living at some distance, was ill. His draught of chloral, prescribed the night before, and of mild dose, was repeated, and as pain did not abate, spongio piline wrung in hot water and sprinkled with two teaspoonfuls of laudanum applied to the abdomen. Suddenly this weakly, fragile lady, who had a positive loathing for food, became insensible, commenced to snore, the mouth wide open, the pupils contracted and insensible to light; shouting, slapping, shaking, splashing with cold water having no effect, nor strong smelling-salts, nor the application of mustard in all directions, hot bottles to the feet and hands; the case became serious, as no pulse could be felt, and the heart's action so feeble, the snoring, the respiration at times suspended. Those who have seen Mr. Irving in the "Bells" will remember the last delineation before the curtain drops, and so it was now—the patient perfectly insensible to the stimulus of the finger down the throat, and administered brandy only bubbled back again. Most fortunately, an adjoining chemist had a powerful galvanic battery, most surprising to relate, in good working order, and it is fully believed the prolonged use of this battery saved this patient's life. As she very slowly and gradually revived, convulsive spasms came on, but what with brandy, beef-tea, ammonia, bromide of potassium, all danger passed away for the time. It has been my lot to battle alone with many desperate cases, but never was anxiety greater than on that July morning in a Himalayan hotel. Out of window was a glorious panorama spread out—of the Doon, 5,000 feet below, the silver streams, the dark jungle, the green forests and crops, the yellow houses, a landslip of russet red—all lit up by the golden sunshine between the showers. Beyond, again, darkly rose the Sewaliks, shutting out the steaming plains. Electricity (it is said), one of the most powerful agents in the treatment of disease, may be useful, useless, or mischievous, according to circumstances. In India, where the nervous system is so often taxed, galvanic batteries are often required; but the climate, or something, continually keeps such armamentaria useless, out of order. Premature labour, tedious labours, post-partum hæmorrhage, ovarian or mammary pain, torticollis, writer's cramp, aphonia, neuralgia, nervous deafness, migraine, toothache, infantile, traumatic, or local paralysis, gastralgia, dyspepsia, sciatica,, rheumatism, tedious ulcers, gonorrhœa, leucorrhœa, lumbago, colic, certain forms of insanity, impotence, constipation, and other ailments are said to be relieved by electricity. The electric cautery has many friends: for epilepsy, and the convalescence of malarial, or fevers generally, galvanism would be of service; for chilblains, or leucoderma, it does not appear to answer, nor for snake-bite stupor. Malingerers strongly object to the remedy, so do hysterical women; but the

case just spoken of was not hysteria, as persons might suggest. A practitioner who has found nitrite of amyl inhaled in five minim doses useful in asthma, cardiac dyspnœa, and convulsions of all sorts, thinks this remedy might have been useful, but this is doubtful, nor have chemists in the mountains every medicine. Nitrite of amyl diminishes arterial pressure, increases frequency of contraction. According to some it acts not on the nervous system, but on the contracted walls of blood-vessels, reducing arterial pressure by diminishing the resistance to the circulation. By others it is said to be useful in angina, asthma, tetanus and neuralgia, acting as a powerful depressant of the reflex motor centres. Dr. H. C. Wood, of Philadelphia, Dr. Chapman, Dr. Talfourd Jones, Dr. Lauder Brunton, Dr. H. Madden, of Torquay (*vide Practitioner*, December, 1872), Dr. Crichton Browne, in the same valuable journal in September, 1874, Dr. Pick also, all praise this remedy—on the idea that the collapse of cholera and that of asthma are similar; that cholera is a contraction of pulmonary capillaries, then why not try nitrite of amyl in this mysterious disease? And Dr. David Smith did give it a very careful trial at Calcutta, but the man died. As for the doses hypodermically injected, the effects produced on the pulse, respiration, and temperature, they will all be found detailed on page 123, vol. viii., of the *Indian Medical Gazette, quod vide.*

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE third meeting of the present session was held on Friday evening, January 7th,

The President of the Royal College of Surgeons, Mr. EDWARD HAMILTON, occupying the chair.

Dr. HENRY KENNEDY then read his paper,

A CASE OF CHRONIC RHEUMATIC ARTHRITIS OF THE HIP-JOINT,

which will be found at page 87.

In opening the discussion,

The PRESIDENT said there were one or two important pathological principles well worthy of notice in the paper, as to whether the disease was really inflammation or not. The opinion of most surgeons was that in its first stage it was inflammation. One of the best authorities, Mr. Adams, had designated it chronic rheumatic arthritis. Dr. Kennedy had alluded to a case of his (the President's) which he had brought before the Pathological Society. In that case they had an extreme example of the disease in an advanced stage in one hip-joint, and in several other joints besides, where the joints presented evidences of increased vascularity, if not of inflammatory action. Taking that view of the pathology of the disease, they could easily see the value of treatment. With respect to the matter of rest, he might mention the case of a lady under his own care. He thought he might say that from the commencement to the end she was afflicted with great pains, and he believed by the use of active and continued exercise she had got completely well, and the disease had passed completely off. The joint was almost as well as ever it was, and she now had no trace of the disease, as she had told him the other day "she had literally walked it off." With respect to the bulging of the acetabulum towards the pelvis that did not occur in his case. The increase in depth was caused by the stalactitic growths on the margin of the acetabulum. The bone was almost perfectly diaphanous.

Dr. BARTON said the case of Dr. Kennedy's was one of considerable interest, on account of the marked relief that followed from the treatment adopted, and in connection with that, he (Dr. Barton) might mention that in the early stages of that disease he had found ease result from the local application of a liniment, which was recommended, he thought, first by a Mr. Smith, of London, some years ago. It consisted of the oleate of mercury combined with morphia. It was a liniment that was generally to be had, and from the record of a considerable number of cases of a similar kind, and in the early stages of rheumatic arthritis, he had reason to think that Mr. Smith's esteem of it was not exaggerated, and that it was a useful help. The fact of its being useful would support the theory that Dr. Kennedy had advanced as regarded the early stage of the disease, viz., that it was inflammatory, which he believed it to be to a certain extent, that was, until the ossific deposit was changed, and in its early stages the vascularity bore a very large part in the disease.

The PRESIDENT inquired whether the patient had any other pain.

Dr. KENNEDY replied that she was threatened with ganglion of the other hip.

Dr. C. F. MOORE observed that he knew a case in which arthritic symptoms came on very frequently from exposure. Acidity of the stomach generally was one of the accompanying symptoms in that case.

Dr. HENRY KENNEDY, in reply, said that the disease might possibly, in his patient's case, be set down to the lady's habits. Mr. Adams, in his work, spoke of wet and cold as specific causes of it. He (Dr. Kennedy) should state that the lady to whom he had referred in his paper was in the habit of working for hours in her garden with wet feet, and totally regardless of the weather or of clothing. Whether such habits had anything to say to the disease in this particular instance he did not take on himself to say, but it was right to mention that she was exposed as he had stated. The President had alluded to the nature of the disease, and he (Dr. Kennedy) believed that Mr. Adams, in his work, gave the different authorities on it. It was certainly curious that there should be such a diversity of opinion with regard to it. The late Mr. Colles had said it was not inflammation, as there was no pus or lymph.

Mr. B. W. RICHARDSON: I beg your pardon. Though it may be somewhat out of order, I must state that I myself have seen suppuration in these joints.

Dr. KENNEDY said he was only quoting Mr. Colles. In one of the few communications he had made to the Society he exhibited the hip-joints of the late Dr. Perceval. They were remarkable specimens of the disease in a degree that very few would see. The sufferings of that individual were very great, and lasted, as it was well known, for years before his death. Though on the other hand, while he showed that particular case, Mr. Colles specially mentioned a significant fact that the hip-joint was, as a general rule, affected by itself. It was seldom seen in connection with other joints. Sir Benjamin Brodie had peculiar ideas about the disease, as to whether it was gout or rheumatism, or a mixture of both, and so had Heygarth as to the disease, about which he wrote. It was strange that there should be such diversity of opinion. Dr. Barton had alluded to a particular preparation which he (Dr. Kennedy) had not used, but from what he knew of it, he would say it would probably be a medicine exceedingly useful if applied round the joint as an ointment. There were many cases in which the use of a moderate quantity of mercury would be beneficial, and he thought a medicine used in that particular way would probably be useful, particularly in the case of a joint, in giving relief. He was glad to hear the President's observation in reference to exercise. He (Dr. Kennedy) had very great doubts at first as to how far his patient should be allowed or prohibited from taking exercise. At first the exercise he allowed her was moderate, but now she was allowed it to the fullest extent.

HIGHER EDUCATION OF WOMEN.

THE Ladies' Classes at University College began on Monday, the 17th of January, the second term of their eighth session. There was a slight decline in the number of students for the session 1874-75, but the first term of the session 1875-76 showed a considerable advance beyond the highest success hitherto attained. In the Michaelmas term, 1874-75, the whole number of individual students was 199; in the Michaelmas term, 1875-76, just elapsed, the number of individual students was 265. The whole number of tickets taken in Michaelmas term, 1874-75, was 257; in the same term of 1875-76 it was 367. This advance has been substantial in more ways than one. The syllabus of lectures issued before the opening of each session offers a full curriculum of study to those ladies above the age of 17 who are able and willing to secure to themselves the advantages of a London College education. To guard against an unwise use of such classes, no girls who are of an age when they should be having daily lessons at home or at school are admitted, except at the request of a teacher from whom they are receiving regular

instruction. Every year the doors are open to women, and they are invited to many studies, but they do not always take all that is offered. Last year there was a deficiency of entries to the classes of mathematics and Latin. This year there is a class of mathematics, there are three Latin classes, and there is a class of Greek. Every subject taught in the Michaelmas term 1874-75 was taught in the Michaelmas term 1875-76. In two subjects there was indeed a change in each from two classes to one, but the additional work taken by this year's students raised the whole number of classes from nine to fifteen. Of the 265 individual students who attended these classes in the term just closed, 3 were attending 5 classes each, 2 were attending 4 classes each, 10 were attending 3 classes each, 63 were attending 2 classes each, 187 were attending 1 class each. The work that has advanced thus far owes what success it has attained to the quiet endeavour simply to meet such demand for a higher education as is found really to exist in London among ladies whose school-time is over. Thus far, without calling one public meeting or raising a farthing subscription, educational resources of a London college, attended by more than 900 regular students, apart from the 600 or 700 boys in the school associated with it, are being made available for the higher education of women, who may take, of all that belongs to their general culture, as much or as little as they are themselves really disposed to take. There are examinations for those who wish to be examined, and certificates to be earned by those who wish to earn them. There are courses of eighteen lectures, and there are courses of 50 lectures. As to subjects, as to length of courses, as to examinations—in all that belongs to liberal education—there is a supply offered from year to year which more than meets the present demand, and is apt for extension as demands increase. That some hundreds of ladies are studying at University College session after session is, no doubt, good evidence of a step in civilisation that has been made within the last ten years; but, so far as this experiment is concerned, the women of London have not yet won all that they can win by simply entering at all the doors that are thrown open to them and taking all they can get. The subjects now being taught are the Languages and Literatures of England, France, Germany, and Italy; Latin in elementary and more advanced classes; Greek, Mathematics, Logic, Physiology, and Hygiene; also English Constitutional History, to which will be added in the next term a course of General English History, and perhaps a course of Physics. Besides these courses, which are for ladies only, four classes in the College (those of Jurisprudence, Roman Law, Political Economy, and Geology) admit ladies as regular students, and all teaching in the Fine Art Department is open to students of both sexes.

The *Melbourne Argus* of September 17 publishes an argument in the Supreme Court in the action of Tate *v.* Fisher, of a question of some interest to medical practitioners. Mr. Thomas Tate sued Mr. Alex. Fisher, surgeon, for assaulting and cutting and wounding the wife of the plaintiff, whereby the plaintiff lost and was deprived of the society and services of his wife. To this the defendant pleaded that the supposed grievances were surgical operations performed on Mrs. Tate by the defendant with her leave. The plaintiff contended that this was no answer to the charge against the defendant. A wife had no power without her husband's leave to allow a surgeon to perform an operation on her; if that were the law a wife might, to spite her husband, get an arm or a leg cut off.

In addition to saying that the operations were with Mrs. Tait's leave, the defendant ought to have also stated that they were necessary. For the defendant it was maintained that a surgeon was not obliged to wait for the sanction of a husband in treating diseases of the wife, because he might be out of the colony, or perhaps he might not give his assent. The Court adopted the plaintiff's view, that besides stating that the operations were with the wife's leave, it should be said that they were necessary for her health, and directed the defendant to amend his pleadings accordingly.

WEDNESDAY, FEBRUARY 2, 1876.

DISEASE GERMS.

On Friday evening week Professor Tyndall lectured to an admiring and enthusiastic audience on a favourite and fashionable topic, "Dust and Disease Germs." Since the appearance of his last letter on this subject (*Times*, Nov., 1874) Professor Tyndall has maintained a prudent silence, attempting no reply of any kind to his critics; but although silent, he has not been idle; aided by an able assistant, it appears much time and attention has been given to the further elucidation of the Dust Theory of Disease. A more carefully conducted and elaborate series of experiments have tended to confirm him in his former views and published statements, and he now believes he is fairly entitled to propound something more than a theory.

It is quite unnecessary to attempt to describe Professor Tyndall's mode of experimenting, for it must be known he would conduct his investigations as become a perfect master of the art; and we content ourselves by merely observing that his experiments were of two kinds: first, he submitted a large number of previously boiled fermentable solutions to the contact of the air of his laboratory, and observed what other investigators have noticed before, that they quickly swarmed with organisms, bacteria, &c.; secondly, he submitted a series of similarly prepared infusions of various animal and vegetable matters to purified air, in chambers rendered perfectly air tight, and after all floating germs had become deposited and fixed to the sides and bottom of the chamber, that these remained free from bacteria and fungoid life of every kind. Pasteur and others have submitted a number of infusions to the same test, and obtained precisely the same results, for so long as they are left undisturbed they neither ferment nor putrefy. Pasteur, however, has gone further, and has shown that while by exposure of infusions to the air fermentation and putrefaction will be set up, similar phenomena may be initiated by a chemical process occur-

ring in the tissue elements of vegetable tissues when placed under certain abnormal conditions; that, in fact, fermentation occurs under the influence of altered chemical (nutritive) processes taking place in unhealthy vegetable tissue, probably just as similar processes are set up by the chemical changes brought about by the particles of finely divided platinum, or even in an atmosphere of carbonic acid, as when grapes undergo fermentation and germinate alcohol and other products.

Professor Tyndall possibly believes that he has applied more rigorous tests than Pasteur, and is therefore justified in asserting that, as all, or nearly all, the infusions exposed to the air of his laboratory became infected in the course of three or four days, he has unmistakably proved that putrefaction and fermentation are due to "a cloud of vital floating germs in the air," and nothing else. Dr. Bastian, however, demurs to his doctrine, because, as he says, admirable as may be Professor Tyndall's results, "in themselves they are altogether collateral, and do not bear upon the question at issue." It is a very easy thing, as he observes, "to get negative results," but "it is rash and hasty to come to the conclusion that his (Dr. Bastian's) are vitiated by error." To prove that this is so he is prepared "to take the boxes employed by Professor Tyndall in his experiments and use them with all the precautions he specifies," and get by careful attention to the preparation of the infusions and the degree of heat to which, subsequent to boiling, they are exposed, a totally different result—show that infusions which, in the Professor's hands, have remained barren, "may yet be made to swarm with bacteria."

Possibly Professor Tyndall has not found, as we have, that by adding the smallest quantity of an alkali—ammonic tartrate, &c.—to his solutions they can be made in a short time to putrefy and swarm with bacteria; but quite apart from this fact, we have proof positive that putrefaction may exist without bacteria, and bacteria without putrefaction. Of the truth of this, as well as results of a striking character bearing upon the independent origin of living matter, Dr. Bastian is preparing proofs, and there for the present we leave this part of the question.

Professor Tyndall has, he tells us, convinced himself that the poison of enteric fever is in no way due to the presence of sewer-gas, but to the floating atoms—organic germs floating in the sewers—which are driven back into our houses. If this be so, we might fairly expect all the inmates will inhale these myriads of unseen germs, and become simultaneously poisoned. But this is known not to be the case, and in all outbreaks of fever there is the greatest possible diversity in the degree of contagiousness, and in the mode of its propagation. Relapsing fever, as Dr. Murchison has observed, is, under certain circumstances, highly contagious, and yet one attack confers no immunity from subsequent attacks. In short, the facts ascertained in connection with the so-called specific fevers are equally capable of explanation in other ways, and far more intelligently than by the action of vital germs.

Bacteria have been found in every tissue of the living body when in perfect health, and we know how rapidly they multiply after death; while neither bacteria nor disease germs of any kind have been found in certain fluids possessing virulent contagious properties. The statement lately made that in the two diseases, relapsing fever and sheep-pox, distinct forms of bacteria have been found, "in no way," as Dr. Murchison justly remarks, "proves any causal relationship between these diseases and the bacteria, and is readily accounted for by the acknowledged fact that the form taken by many minute growths depends not upon the germ, but upon the nature of the medium in which it grows. Indeed, the observations which have been made on the spirilla of relapsing fever are strongly in favour of this view; they are present in the blood during the paroxysm, but disappear before the crisis; are absent during the intermission, but return with the relapse of fever, and again disappear before the second crisis. It seems difficult to account for their appearance and sudden annihilation twice over, except on the supposition that the soil was suitable for their development during the febrile process, and unsuitable when the febrile process was complete."

From these and other valid considerations we are led to conclude that, although Professor Tyndall's experiments show that the air is at all times loaded with myriads of organised bodies, they do not go far to establish the correctness of the germ theory of disease. Prof. Tyndall, however, spoke of the extreme minuteness of the ova or spores of these bodies, and of the impossibility of detecting them by means of the microscope. Notwithstanding this assertion, we easily detect the presence of bacteria in the fluid secretions of the mouth of persons in perfect health, while with much higher powers we are *unable* to detect any moving living organisms in the blood or fluids of fever patients. Another fact of great importance is that the majority of patients who suffer from contagious diseases recover. This, as Dr. Richardson pertinently observes, should scarcely be so, if, as Prof. Tyndall says, these clouds of organic germs that float about in myriads "are reproduced so rapidly, and possess such persistency of life, it is hard indeed to see why there should not be an increase of them, from which there could be no escape for man or animal, and by which in time the world would be depopulated." To avoid these deleterious germs houses should be constructed on the principle of his air-tight boxes; but, unfortunately for human beings, they cannot exist without a constant supply of air, and thus are placed between a Scylla and Charybdis. We contend, however, that the weight of evidence is much in favour of the independent origin of contagious diseases, as pyæmia, erysipelas, diphtheria, enteric fever, &c., while it feebly gives support to the views entertained by Prof. Tyndall; further, the occasional presence of bacteria in specific fevers and other diseases is not conclusively in favour of the theory he would establish: indeed, we regard the presence of bacteria, or other organic germs derived from without, not as a morbid process, but rather as the normal result of the operation of those laws which regulate the degeneration of the tissues, the breaking up as it were of organised matter. Some of the products of this process, under certain circumstances and conditions, are no doubt capable of inducing morbid actions, but the process itself the pathologist will refuse to class as disease.

THE PUBLIC PRESS AND QUACKERY.

We regret to see that, notwithstanding much has been done within the last few years to check the exhibitions of quackery that used to disgrace the columns of our newspapers, a thriving trade is still carried on by pandering to the credulity and taking advantage of the misfortunes of mankind. And we still more regret to find that some of the worst forms of knavery and imposture still receive encouragement and flaunt their impudent pretensions in those quarters where one would expect to see rather a public exposure of the various tricks that are practised in order to rob the pocket and ruin the health of the more ignorant and weak-minded of the community.

Few of our readers can have forgotten that within the last few years the advertising columns of the whole daily press, from the *Times* downwards, were freely sprinkled with the indecent announcements of obscene quacks, many of whom were making enormous incomes by a system of extortion and terrorism scarcely credible by the uninitiated, and which they were able to carry on with impunity in consequence of the moral weakness and timidity of their victims. It is also well known that these disreputable persons are still able to pursue their nefarious trade, mainly by reason of the assistance they receive from a considerable number of provincial newspapers, which are even at the present time disgraced by whole columns of quack advertisements. There can be little doubt that the proprietors of these papers are in most cases fully aware of the infamous nature of the traffic which for the sake of paltry gain they aid and abet. The true character of what may be called the most loathsome and culpable forms of quackery was first publicly exposed, years ago, in a series of letters in the pages of the Medical Press. It is high time that these baneful advertisements were swept away from the provincial, as they have been from most of the metropolitan papers, and, in the interest of public health and morality, we think it so desirable that those papers should be purged of *the filth* with which they are polluted, that we purpose *publishing*, from week to week, a black list of the offending papers, together with an *exposé* of the nefarious trade which they knowingly assist.

But although the more outrageous and scandalous kinds of charlatanism are, happily, not so rife as they formerly were, less harmful, but yet very objectionable, forms of quackery and humbug prevail to an almost incredible extent, and unfortunately reaches its victims through the very same medium as that which we have just seen to be such a powerful tool in the hands of more notorious quacks. We refer particularly to the pretentious announcements and carefully disguised puffs that emanate from a certain class of medical men, advertising dentists, and other specialists, and which not only disgrace the professions to which they respectively belong, but often put in jeopardy the health and comfort of those who are foolish enough to patronise them. Perhaps one of the most glaring instances of this kind, and one of the most artful pieces of puffing we have seen for some time, is, we regret to say, to be found under the cloak of an editorial article in one of the most respectable of our papers, the *Daily News*. When we first caught sight of the large-typed title which headed this article we thought it was the announcement of some great political event—nothing less than a solution of the great Eastern question, or some extraordinary occurrence during the tour of the Prince of Wales. We were, however, soon undeceived, and were not a little astonished to find that it was an article in which the writer discoursed with all the eloquence of which he was master on the "Mysteries of Dentistry," and of the wonderful machinery and talents at the disposal of that particular gentleman whom it was the object of the writer to "take by the hand" and show up to an admiring British public as a paragon of dental skill and ingenuity! It is rather a joke that the article opens with an affected disclaimer of anything like quackery, and the naïve admission that "drawing teeth is often an excellent pretence for drawing money from the pockets of innocent patients," and that "there is no profession in the world so entirely unprotected against the charlatan as that of dentistry." Of the truth of that ingenious observation we need scarcely remark that this audacious puff affords the best proof. We are then treated with an elaborate description of Mr. ——'s establishment. The writer had heard of many wonderful things in connection with the "mysteries" of dentistry, but not until he had "been fortunate enough to obtain admission to one of the most favoured of these establishments, the dental surgery and factory" of that gentleman—of course, specifying his name and the number of the street where he is to be found—not until then had his eyes been open to the marvels which lay concealed within the mansion of an advertising unqualified dentist. The next dish by which the mental appetite and gullibility of the reader is tantalised is the flowery description of the "handsome frontage," the "beautiful aquarium," the "tastefully arranged exotics," and the admirable "appointments" of this wonderful place. "Leaving the surgery and passing through a long corridor or covered way adorned with shrubs and flowers, we ascend a few steps and find ourselves in the dental factory." Admirable! What a paradise for poor mortals afflicted with such mundane torments as those of a common toothache. We will not fatigue our readers by taking them through the long descriptions of the various machinery, furniture, and other paraphernalia of this dental factory, and which is given with all that cant which the accomplished writer of puffs knows so well how to use. We have already said enough to let the reader see the real gist and purpose of the article. We may, however, inform him that "a wondrous facility for extracting teeth without pain is not the only reputation which this gentleman is zealous to preserve; he is equally careful that every set of teeth which goes forth from his factory shall be an additional memorial of his reputation." Nor can we help noticing that the artful writer is able to make capital out of the impudent prospectuses which advertising dentists send out by thousands, and he has the unblushing effrontery to dignify them with the name of "little books of popular instruction," and to say that "quite a little book trade is being carried on in the apartment devoted to what we may designate the publishing branch of the establisment"!

That all this quackery and humbug will produce a good deal of the desired effect we are sorry to be able to

admit, and we still more regret that the length and editorial form of the article and its prominent position in one of our best morning papers will succeed only too well in leading the unwary into the belief that the article was written in good faith, and that instead of being a well-planned puff of one of those notorious advertising dentists with which the metropolis abounds, it is an honest description of the present state of dental science, and refers to some really eminent surgeon-dentist. The bait will no doubt take. Crowds of credulous patients, attracted by the plausible announcement, will flock to this abode of beautiful exotics, flowery corridors, models of jaw-bones, and advertisement literature, so that whatever was paid for the insertion of this elaborate puff will be returned to its enterprising proprietor a hundredfold. In another column we print the protest which this disgraceful article evoked from a member of the profession; and also the sole excuse which the managers of the paper in question are able to offer in condonation of the injury which they have inflicted upon the public.

The fact is that quackery in any form is a parasite of society which appears to be difficult to kill. It is like one of those parasites whose vitality is so great and whose progeny is so numerous that as fast as they are stamped out in one direction they spring up in another. And like those pests of the physical world, there appears to be always somewhere present a soil which is favourable to the growth of the moral evil, and without the removal of which we cannot expect to see the evil itself disappear. But how deeply quackery of all kinds is rooted in our social system, and what a difficult task it must be to get rid of it, is shown not only by a consideration of the various conditions by which it is fostered, among which the general credulity of mankind is one of the most influential, but also by the many instances that from time to time crop up to remind us of the gullibility of the public, and of the various ways in which snares are laid to entrap the credulous and unwary.

PRESCRIBING CHEMISTS.

An action has been recently brought by the Apothecaries' Company against a chemist and druggist in Shadwell to recover a penalty of £20 for an alleged infringement of their Act of 1815 by that chemist practising as an apothecary without having obtained the necessary certificate from the Company. The case raised an important question as to the right of chemists to prescribe medicines over their counters—a practice which, it was admitted, is very general throughout the kingdom, especially in the poorer districts. The defendant stated that in all serious cases the parties were attended by the *regular practitioner who was in partnership with him;* but he admitted that in minor cases he had inquired the nature of the illness, and had given the medicine suited to it without the intervention of his partner.

Baron Bramwell, in summing up, remarked that the "Act was strict in its terms, and that the jury were bound by it. . . . If a man entered a chemist's shop and asked for something to cure a bad headache, and the chemist gave him a draught, without doubt the chemist would technically infringe the terms of the Act; but it would be very unreasonable if the Apothecaries' Company were to interfere in such a case."

The result of the action was that the jury returned a verdict for the plaintiff.

It is well known to the profession to what an extent the prescribing of medicine over the counter by chemists is carried on, and, notwithstanding the strictness of the terms of the Apothecaries' Act, the law has very little influence in checking the practice. It is, in fact, a practice which the public encourage, which the profession connives at, and which the law cannot easily reach. With respect to the public, we cannot be surprised that hundreds of the poorer classes ask the chemist to relieve their little ailments when we consider that a large number belonging to the more educated portion of the community are in the habit of doing the very same thing. Indeed, many appear to be under the impression that the druggist is well acquainted with the action and uses of the drugs which he sells, and that, in trivial cases, he is as well able to prescribe a suitable remedy as the doctor himself. And herein perhaps we must in a great measure look for an abatement of the evil, for not until the public find what time they lose, or even what risk they run by resorting to chemists for medical advice, can we expect to see this long-established custom given up. But not only have the public given great encouragement to the practice, but, as we have just said, the profession itself has to a certain extent connived at it, and is, we may add, partly responsible for it. The profession has never adopted any well-concerted measures to put a check upon it, and by so many of its members keeping open shops and dispensing their own medicines, it has laid itself open to the retort that if chemists now and then trespass upon the province of medical men, the latter interfere far more openly, and to a much greater extent, with the business and profits of the chemist. At the same time, such are the difficulties of the question that we much doubt whether the druggist and medical practitioner will ever be able to keep entirely within their respective provinces, and limit their practice to that for which they are respectively qualified. Even if every member of the medical profession tried to confine his practice to prescribing, and every chemist to dispensing only, there is reason to believe that the good intentions of the chemist would have to yield to a strong pressure from without. To have to consult on every trivial occasion a medical man, have a prescription written, and then to take it to the chemist, is both a more costly and more inconvenient process than that of dropping into the chemist's shop and having a bottle of medicine made up at once, and at half the cost; and consequently one effect of a change, otherwise so laudable and dignified, would probably be to drive half the patients who now resort to the shop of the qualified surgeon into the hands of the unqualified chemist. For this and other reasons it is doubtful whether the habit which chemists and medical men have of infringing upon each other's ground can ever be entirely got rid of, and the only thing the public and the legislature have to guard against is that the practice be so restricted that little or no harm can be done. As Baron Bramwell very justly observed, it would be unreasonable to bring an action against a

chemist for giving a bottle of medicine to relieve his customer's headache. But when, as is often done, the chemist undertakes the whole treatment of a case, either alone or under the protection or cloak of a partnership with a medical man, or prescribes strong remedies for a complaint of which he knows nothing, or even visits a patient, the case is very different, and too strong measures cannot be taken to prevent such practices. For this reason we should like to hear that such actions as that on which we are now commenting were more frequently brought against a certain class of chemists than they really are, inasmuch as the occasional infliction of a penalty of £20 would deter them from undertaking the duties of a regular practitioner, and confine their offences to such as are of a more venial nature, and such as the law cannot so well take cognisance of.

Before, however, we leave the subject, we cannot help feeling ashamed that in a profession like that of medicine there is a large class of medical men who are low-minded enough to enter into a sort of agreement or partnership with chemists, and by that means to directly encourage those very practices which they ought to be the first to denounce. Such men are more to be blamed than the chemists, and it would be a good thing if they were themselves liable to a penalty, or even to be struck off the "Register." It is evident that, notwithstanding our preliminary examinations are of a higher standard than they used to be, they are not too high to prevent gentlemen entering the profession who do not hesitate to sacrifice their reputation and self-respect to a little paltry gain, and to bring discredit upon a noble and honourable calling. It is true that many of these disreputable individuals belong to a past generation, and gained admission into the profession when its portals were more widely open and less vigorously guarded than they are now; and therefore we hope that as fast as these ornaments of a bygone period break down they will be replaced by others of whom we shall have more reason to be proud, or whom we can at all events respect.

Notes on Current Topics.

Hastings Water Supply.

THE imperfect water supply of Hastings is producing a good deal of dissatisfaction among the ratepayers. A large sum of money is about to be expended to improve the supply, but the Town Council holds out against the "constant water service."

As the water supply of a town is entirely a hygeian question, we should recommend the medical men of the neighbourhood to give the matter their fullest consideration; to them we must look to make known to the ratepayers such measures are necessary to health, and we conclude that the voice of the ratepayers will have its influence even upon a Town Council. The health of Hastings at the present time is not up to the standard, and if any epidemic should occur there the town will receive a shock from which it will not readily recover itself.

Certificated Officers of Health.

REFERRING to the recent Acts and the relations of medical officers of health to the public, our excellent contemporary the *Leisure Hour* in the number for February remarks:—"Prevention better than cure" is so trite, so true, so old an adage, that the wonder is that only lately, under the term, "Preventive, or State Medicine," its importance as regards sanitary matters has boen recognised, and that attempts to enforce its principles have been made. The consolidation of the Nuisances Removal Act, the Public Health Act, 1848, Sanitary Acts, 1866 and 1872, resulted in the Public Health Act of last seasion, and the recommendation of the appointment of well-trained and specially-qualified medical men for this department as "officers of health," especially to large districts. Having sufficient salaries, they are debarred from private practice, and thus can act independently, and not allow the law to become a dead letter, as is too frequently the case where to so-called officers of health, not under the Government Act, small salaries are paid to do nothing, or next to nothing. The university certificate, granted after thorough examination, will serve to assist the judgment of those public bodies in which the choice of officers of health has been invested by the law.

Can a Surgeon claim for Services rendered by an Unqualified Assistant?

A MEDICAL question of some importance was decided at the Clerkenwell County Court last month.

Dr. E. Godfrey Purcell, of King's Cross Road, sued Mr. Jackson for two guineas for services rendered.

Defendant had engaged the plaintiff's assistant to attend his wife during her confinement, under the belief that he was duly qualified. The assistant also attended the infant when born, which afterwards died. Discovering that the assistant was unqualified, defendant refused to pay plaintiff's charges.

The Judge said that neither Dr. Purcell nor his assistant had any legal claim upon the defendant, and he therefore gave judgment in favour of the defendant, with costs.

Another Death from Chloroform.

AN inquest was held at Stafford, on Thursday, on the body of Jeremiah Tooth, a labourer, who had died in the infirmary while under the influence of chloroform. Dr. Reid, the house-surgeon, said he administered the chloroform in the presence of five other medical men, as the deceased was about to have the arm amputated. He had previously examined the deceased with the stethoscope, and obtained no evidence whatever of heart disease. Three drachms—about an average quantity—were administered, and while the deceased was taking it his pulse stopped, and he died instantly. The usual methods of restoring animation were adopted, but without success. A post-mortem examination showed that the heart was larger than usual, and that there were other traces of disease. Dr. Day and Mr. Greaves were of opinion that death resulted from paralysis of the heart. The jury returned a verdict in accordance with these facts.

Royal College of Surgeons of England.

Owing to the lamentable demise of Mr. Gascoyen, a vacancy occurs on the Board of Examiners at the College which must be immediately filled up. We regret that some of our contemporaries have considered it within their province to nominate certain gentlemen as the most fitted for the vacant post. It is perhaps the function of the press to direct public opinion and to offer suggestions even to a body like the Council of the College, but the nomination of a candidate for the office of Examinership will most assuredly not influence the members of the Council in *favour* of his election. Should the nominee not be elected, he is unfairly placed in a conspicuously invidious position, and the journal is deservedly stultified. Such a nomination, moreover, is a reflection upon the judgment and impartiality of the Council, a sufficiency of which qualities to arrive at a fair decision in the present case will hardly be denied them by our contemporaries.

Artificial Milk.

The *American Journal of Pharmacy* says the best substitute for mother's milk, according to Beno Martiny, is the yolk of chicken egg, which weighs, on an average, fifteen grammes, and when diluted with 57·1 grammes of water of 100° and five grammes of milk-sugar has nearly the same composition as the milk in the first period of lactation. Subsequently, the fat and protein decrease, and to one yolk may be added one hundred grammes of water and six grammes of milk-sugar.

Conversion of Butter.

The *Glasgow News* has just published the almost incredible result of an inquiry into trade practices, in the reclamation of butter, to which its attention had been directed by a trade circular some time back issued by a firm established in Leith and Glasgow, offering to reclaim old butter, removing any taste of tallow, grease, and also bad smells, &c., at the same time slightly increasing the weight, at the rate of 7s. 6d. per cwt. if in casks, or 10s. 6d. per cwt. if in Irish lumps.

In order to test these promises, the *Chemist and Druggist* says that two gentlemen were commissioned to make preliminary inquiries, as probable customers. They were informed that grease-butter, or even "scrapings" (a technical term for refuse butter), could be turned out either in the form of finest tub butter or Irish lumps, according to the quality of the stuff originally sent; that butter treated by this process had hitherto given entire satisfaction, except in one solitary instance, that of a Liverpool firm, which was particularised; also that at the Leith works of the firm the amount daily sent out was, on an average, 35 cwt. They therefore agreed to send a sample for treatment, and the following course was adopted:—A Coleraine butt of grease-butter, sold for lubricating purposes, was purchased, and there was incorporated with it a small quantity of Russian tallow, some of which had passed through the printing-office machinery, and had absorbed particles of blacklead and mineral oxides from contact with the bearings of the shafting. A common tallow candle, from which the wick had been removed was also added. The compound and the tallow candle were carefully melted into the grease-butter, and, notwithstanding the offensive character of these additions, the butter was so decomposed as completely to disguise them. Thus prepared, the firkin was sent to the works, with a request that it be turned into "lumps of a bright yellow colour for sale in the English market, and with a stubble-grass smell." The firm characterised the sample as "very bad," but promised to do their best with it. In the course of a few days the butter was returned re-converted, its weight on return being 51½lbs., against 47½lbs. when sent for treatment. Were it not for some mineral particles discovered on strict examination it would hardly have been possible to have identified the sample, so remarkable was the change in the whole composition. These statements are verified by the city analyst, who described the original butter, as "in the last stage of rottonness, having a disgusting odour, covered with green mould, and maggotty." If it be true that from these works 3,920lbs. of this converted butter has been issuing daily to all parts of the kingdom, we may all indulge in a shudder at the thought of the possible lubricants on which we have been regaling of late.

The International Medical Congress of 1877.

The Committee of the International Medical Congress have issued a circular, in which they remind the profession that the meeting of the Fifth Session of the Congress for 1877 will be held in Geneva, and an Organisation Committee has been accordingly appointed by the Medical Society of the Canton of Geneva, acting with the Scientific section of the National Institute.

The Congress will occupy a week, commencing from the 9th of September, 1877, and all communications as to its affairs must reach the Committee before the 1st of June next, being addressed to Dr. Prevost, the General Secretary.

The Emperor of Brazil's Grandchild.

Some time ago we mentioned that Professor Depaul, of Paris, had been called to Rio Janeiro to attend the Imperial Princess, the Countess d'Eu, in her confinement. After nine years of sterile married life, the Countess, the daughter of the Emperor of the Brazils, became pregnant after consulting Dr. Depaul in Paris, and following the treatment he recommended; but the child which was born was born dead. She became again pregnant, and this time the Emperor solicited Depaul to come out himself, and conduct the delivery. On his arrival at Rio Janeiro he met with a most frigid reception from almost every one except the immediate attendants of the Princess. The newspapers were against him, and the native physicians gave him the cold shoulder. On the day of the accouchement he found himself at the bedside of the Princess alone and without assistance. After a thirteen hours, labour, which had to be ended with the forceps, a baby weighing twelve pounds was at last brought into the world; but for an hour it was doubted whether it would survive, and it was only after artificial respiration and other measures had been vigorously tried that it gave signs of life. However, it is now a healthy child. The most curious and amusing feature about Dr. Depaul's visit was

the revulsion of public opinion in his favour when the successful result of his visit became known. The papers praised him, his *confréres* congratulated him, and the academies and scientific bodies sent him crowns and addresses; he was invited to banquets, and was *feted* in a wonderful way. "After the event," says Depaul, "my room was never empty from morning till night, and I was obliged, in spite of a determination to the contrary, to give consultations. In less than eight days, 15,000 francs worth of piastres were laid on my table as fees." Professor Depaul has certainly good reason to be satisfied with his trip across the ocean.

Unappreciated Doctors.

WHO is there among us who cannot point to a practitioner who has tried to establish himself in more than one neighbourhood, and failed—failed, not because of incompetence—not from want of merit—but from some cause which has appeared to him quite inexplicable? He sees men of the same age and standing, perhaps from the same school as himself, driving their broughams, with a large practice at their backs, while he sits at home hopefully expectant that a fee will turn up sooner or later, and wonders at the success of others. Has not the absence of that suavity which commands, and cheerfulness of manner which makes sunshine in the room of the patient, much to do with the want of appreciation so keenly felt by the unsuccessful practitioner? All the degrees and acquirements in the world will not atone for a sour, unsympathising disposition. 'Tis true that instances can be quoted of great men having attained high positions in the profession notwithstanding the possession of a morose and uncultivated style, by sheer force of extraordinary abilities; but these are only given to a few; and it would be well if those who are still mourning their position as unappreciated doctors would look at the matter in its proper light. Perhaps the following remarks which appeared in the last number of the *Atlanta Journal* may assist them:—

"*No* honest and industrious physician, be he ever so *humble* in his capacity, can follow his vocation diligently for a twelve-month in any locality and fail to impress *somebody* with a just estimate of his services. If he will but content himself with the progress made, and continue his efforts patiently and perseveringly, he will surely add friend to friend and patron to patron, until at last peace and plenty shall smile upon his honest and earnest endeavours.

"It is no uncommon error for medical men to find the widest discrepancy existing between the esteem in which they are held by the community and the self-estimate of their own capacity. Such n are the victims of a cold, unfeeling world. They are appreciated by the public. They become per consequence soured with the world, and very naturally resent the injustice, the blindness and ignorance of mankind, who fail to discern their supposed merit and capacity. We verily believe that these professional, self-constituted martyrs to the coldness, blindness, and ignorance which surrounds and engulfs them are but too often the architects of their own mal-fortune. Nobody chooses a soured misanthrope for his companion; nobody takes a mountain of self-conceit for his bosom friend."

Unsuspected Sources of Infectious Diseases.

WE have received a pamphlet on some unsuspected sources of infectious diseases, a paper read before the Public Health Department of the Social Science Congress at Brighton by Mrs. M. A. Baines. It contains many useful hints on domiciliary sanitary inspection. After referring to the "ash heap nuisance," that is, the danger arising from the admission into the house of poisonous gases generated by the putrefaction of vegetable and animal matters which have been thrown into the dust-hole, it is suggested that householders will not only prevent the formation of the poisonous gases, but will also find it a great pecuniary saving, if they adopt the very simple plan of having a wire grating placed on the top of the dust-bin, and so arranged that it would not be in the power of the servants to move it; in this way, at the cost of a few shillings, a very large amount of coal might be annually saved.

It is not suggested in the pamphlet what is to become of the waste if pig-tubs are done away with, and nothing but cinder-dust is allowed in the dust-bin, but concludes that there ought to be no waste, in fact, nothing should be allowed to go out of the house except to add to the dietary of deserving poor. There are, however, a few things which even deserving poor would not relish, and which housekeepers have a difficulty in getting rid of, the refuse from game, chickens, &c., and vegetable cuttings. They cannot be burnt, for the odour is too unpleasant through the house; it is dangerous to throw them in the dust-bin in consequence of the development of poisonous gases; and they cannot always be buried in the garden, for gardens in towns are rare luxuries. A little advice upon this point would be found useful.

On Jaborandi.

DR. FELIPPO CESARI, of Rome, in the *Gazeta Medica*, of that city, has an article entitled "Physiological Experiments and Clinical Notes on the Polycarpus Pinnatus, or so-called Jaborandi," in which he comes to the following conclusions:—1. That the jaborandi of Continho has an elective action on the salivary glands. 2. That it has a secondary action, but less constant and copious, upon the sudoriparous glands. 3. That it has well-marked diuretic action. 4. That it produces no effect whatever on the circulation, nor on the generation of heat, nor (except in an unimportant degree) on the respiration. 5. That its action is most efficacious when it is injected into the veins. 6. That its after-effects are distinct debility, with an imperious thirst, directly proportioned to the action of the emunctories. These effects, however, are transitory, and soon disappear under restorative diet.

Brand's Preparations of Meat.

WE have received from Messrs. Brand and Co. samples of their Essence of Beef, Concentrated Beef Tea, and Meat Lozenges.

The essence of meat is said to consist solely of the juice of the finest beef extracted by a gentle heat, without the addition of water or of any other substance whatever. These preparations contain both the salts and the nitrogenous compound of meat, so that invalids who are unable

to take meat, and who indeed could not digest it if taken into the stomach, have the opportunity of taking it in a fluid form in the shape of the essence of meat, a form readily absorbed into the vessels.

These preparations, but more especially the essence of meat, are now used very largely. They are decidedly the most nourishing that are in use; they are agreeable to the palate, and may be recommended with confidence.

THE town of Grimsby is to have an hospital; the plans and site have been decided.

DURING the past week her Majesty the Queen has sent her annual presents of game to most of the London hospitals.

PROFESSOR ERASMUS WILSON, F.R.S., commenced his course of lectures on Dermatology at the Royal College of Surgeons of England yesterday afternoon.

M. DENUCE communicates to the Académie de Médecine of Paris a case in which he successfully performed external hysterotomy on a woman, whose life was endangered by excessive hæmorrhage, due to old-standing irreducible inversion of the uterus.

THE English Pharmaceutical Society has prosecuted a beerhouse keeper for selling a sheep-dipping composition containing arsenic. The judge seemed very reluctant to convict, but the law was too strong for him.

GERMANY, with a population of 42,000,000, last year graduated six hundred and sixty physicians, rejecting one hundred and eighty applicants. In the same time the United States, with a population of 40,000,000, graduated three thousand physicians, and remorselessly turned them loose upon the community.

LONDON pauperism continues on its decline most satisfactorily. The last weekly return shows the number of paupers to be 88,948, of whom 37,261 were in workhouses, and 51,687 receiving out-door relief. Compared with the corresponding week in the years 1875, 1874, and 1873 these figures show a decrease of 10,968, 17,960, and 22,742 respectively.

IN the Foundling Hospital, St. Petersburg, where most of the public vaccination is carried on, calf lymph has been used side by side with human lymph for the last five or six years. It is said to be equally protective, and failures in primary operations have, by care and perseverance, been reduced as low as two per cent.

THE *Medical Examiner* gives currency to a rumour that at the next meeting of the Medical Council the representative of the Queen's University will protest against that part of the report of the visitation of last year which concerns general education. The professors consider that as the visitors were not present at any examination in general education at Belfast, Cork, or Galway, the visitors had no right to express an opinion upon the point. On the other hand, the visitors believe themselves justified in inferring that the standard of education in arts was not so high as it should be from the style in which the answers to the medical questions were conveyed.

THE following Circulars relative to the Army Medical Department have been issued from the War Office:—

"*Retirement.*—Whenever medical officers who are responsible for hospital equipment and provisions ask permission to resign their commissions while on full pay the papers containing their application to retire will be accompanied by a joint certificate from the principal medical officer and the District Commissary-General to the effect that the charge of hospital equipment and provisions has been correctly given over and that there are no deficiencies unpaid.

"*Surgical Instruments.*—Medical officers upon attaining the rank of Surgeon-Major will not in future be required to provide at their own cost a capital case of instruments, but it will be incumbent upon all executive medical officers to provide themselves with, and keep up at their own expense, a case of pocket instruments of an authorised pattern, which will be shortly approved. This case will be carried in the regulation pouch. Paragraph 1, clause 23 (page 87), of the Medical Regulations of 1859 will be amended accordingly.

"*Epidemic Disease.*—During the prevalence of an epidemic disease among the troops or their families, principal medical officers will forward a weekly return of such cases, on War Office form 1,033, to the Director-General of the Army Medical Department."

THE Solicitor of the English Pharmaceutical Society had reported the proceedings which he had taken on behalf of the Society. The report included a lengthy correspondence with reference to the duties of district registrars of births and deaths to transmit to the Registrar of the Pharmaceutical Society notice of the deaths of any chemists and druggists in their districts. A letter having been sent to the registrar at York, calling attention to an omission to send notice of the deaths of five chemists in that city, the superintendent registrar of York had sent up five certificates for which the usual charge of 2s. 6d. was made, and also a charge of 1s each for search. This latter charge being disputed, the superintendent registrar threatened a County Court summons, and this lead to a correspondence with the Registrar-General, who supported the view of his subordinate, and also appeared to misunderstand the language of the Pharmacy Act itself, inasmuch as he gave it as his opinion that the Act only required registrars to forward certificates of death of "pharmaceutical chemists and druggists." The correspondence had been submitted to the Solicitor with a view to ascertaining what course could be adopted to ensure the issuing of proper instructions by the Registrar-General to his subordinates throughout the country. The Solicitor had made several suggestions, one of which was that he should have an interview with the Registrar-General to lay before him the correct interpretation of that provision of the statute. After considerable discussion this suggestion was adopted, and the President and Registrar were requested to accompany the Solicitor.

Our youthful contemporary the *Medical Examiner* has espoused the policy of an outcry against the rendering of gratuitous service by hospital surgeons to the extent to which it is now given, in which policy we are entirely in accord with the *Examiner*. In its issue of the 20th ult. it makes a statement respecting "medical purchase in Dublin," which is not quite correct, not quite fair to Dublin hospital medical officers. It says "that regular money payments are generally exacted from the newly-appointed members of hospital staffs in Dublin. On attaining his post, after a severe struggle, the aspiring young physician or surgeon is obliged to pay over to his predecessor a sum varying from £500 to £600, and when his retirement comes in due course, the regulation price is handed to him by the successor to his vacancy. . . . Whatever the explanation may be of a system which is probably merely the cumbrous remains of some extinct superstition, the significant fact remains that Dublin hospital officers are not only unpaid, but have actually to secure their appointment by an annual contribution of £25."

The first part of this statement was true at one time, but is incorrect as regards the present *status quo*, most of the hospital appointments being now made without any consideration of money. For the hospital where a purchase has most recently been made, it is right to say that the institution was started and carried on for many years at the expense of the medical offieers, who thus bought in actual hard cash a vested interest in it. That interest, now that the hospital is self-supporting, has recently been ceded by them, and is in course of gradual extinction. It is not true to say that Dublin hospital surgeons pay £25 a year for their places. It has been in times past the habit to pay over a much larger sum than this yearly outlay would represent, but in consideration of their services Dublin hospital surgeons are always authorised to divide the pupil fees amongst themselves, and thus they receive usually from 6 to 10 per cent. on their investment.

Correspondence.

THE PUBLIC PRESS AND QUACKERY.

The following is the correspondence referred to in the leading article entitled "The Public Press and Quackery."

To the Editor of the "Daily News."

Sir,—I beg to call your attention to a long article in a recent issue of your paper, headed "The Mysteries of Dentistry," which it appears possible was inserted without your knowledge or consent, for though printed in the form of editorial matter, it is obviously a mere puff of the quack dentist to whom it refers, and its style is sufficient to show that it was composed by no member of the staff of your journal. Had it appeared in the usual manner, as a paid advertisement, I could, perhaps, have said nothing upon the subject, but articles of that kind, in such a form, are especially calculated to injure the dental profession, and to mislead the public; and, moreover, they cannot be inserted in a respectable newspaper with ultimate profit to the proprietors, for they tend to destroy its influence and to degrade it in the estimation of all its more intelligent and educated readers. Feeling that you would not knowingly permit your editorial influence to be used in this way for the promotion of an unworthy object, I am led to appeal to you in the hope that you will allow me to explain why such articles are objectionable, and why, therefore, they should be excluded from your columns for the future.

Dental surgery forms a recognised special branch of general surgery, and those wuo practise it, and who desire to take an honourable position among their brethren, are required to possess the licence in dental surgery of the College of Surgeons, or some similar diploma, and they are expected to conform to those rules of conduct which are observed by members of every profession. Persistent violation of these rules by a qualified practitioner—a rare occurrence—results in his degradation and consequent exclusion from intercourse with his professional brethren; persistent violation of them by an unqualified practitioner, who might otherwise remain free from suspicion, places him at once in the category of disreputable quacks.

Among unprofessional acts the use of advertising puffs, in order to obtain practice, is considered one of the most flagrant, and it is sufficient to cause the offender's expulsion from any association of professional men. The Odontological Society of Great Britain, which consists of a large number of the most eminent dentists, has the following among its bye-laws:—

"Persons who advertise in the public journals, or by circular, either their profession, or their professional attainments or public appointments, or anything relating to their mode of practice or charges, or who expose for public inspection specimens of operative or mechanical dentistry, or conduct their practice in any way which in the opinion of the Council of the Society is derogatory to the respectability of the profession, shall not be considered eligible for nomination as members."

The peculiar obnoxiousness of this offence may be easily accounted for. The services of a professional man are essentially personal, and superiority in their performance can be due alone to superiority of individual education, genius, or skill. Now, it may be safely asserted, that when unusual merit really exists on the part of a practitioner, or when, by original research or experiment, he has made an advance in his department, his talent and work will be acknowledged by the profession, and every due honour will be conferred upon him. Professional recognition of this kind invariably leads to public fame, and a proportionate increase of practice will certainly follow. On these grounds alone, it is therefore probable that no professional man, who can with truth boast of more than average skill, or of more than ordinary success in the treatment of his cases, will attempt to make a connection by advertising. But there are other reasons which should prevent him from so doing. By such conduct, as I have already said, he loses professional caste. In his advertisements—unlike the tradesman who may legitimately seek custom by praising his goods– he is obliged directly or indirectly to vaunt the superiority of his personal acquirements. Self-praise invariably indicates the vulgarity and bad taste, or the folly of the boaster, and leads to his being lowered in the estimation of his associates, even when the gratification of vanity alone, and not gain, is the object; and thus it is that the puffing professional man, manifesting as his least offence a want of self-respect and gentlemanly feeling, becomes at once degraded. But since, as it has been shown, a really talented practitioner would be injured rather than benefited by the proclamation of his merits by means of advertisements, and since no honourable man, even for the sake of great pecuniary gain, will sacrifice his reputation, and render himself an outcast from his profession, the disgraceful act of using puffs to obtain practice serves to indicate in most cases something more than that the offender is devoid merely of gentlemanly feeling. It may, as a rule, be taken to prove that, being deficient in some necessary qualification, he is in truth incapable of making a practice by legitimate means; that, unlike the really skilful practitioner, he is unable to rely for support upon the recommendation of those best able to judge of his acquirements, namely, the patients whom he has treated, and the members of his own and other branches of the profession; and that he is thus compelled to advertise in order by attracting a succession of patients from amongst strangers, to prevent the extinction of his practice, which would otherwise speedily be brought about as a consequence of his incapacity, together with the number of his manifestly unsatisfactory cases. To this must be added, that being incompetent, careless of reputation, and only anxious to make money, the charlatan not uncommonly is found to be equally dishonest in his professional dealings as he is disreputable. I need not occupy your time by demonstrating more completely the truth of these statements—they will be corroborated by every professional man, be he physician, surgeon, or dentist.

It must not be supposed that the dental quack, however incompetent and dishonest, is powerless to inflict greater injury upon his patients than the extortion of enormous fees for badly made artificial teeth. Dental diseases give rise to extreme

pain, and are often concerned in the causation or aggravation of grave local and constitutional affections, and when science is ignored, or their treatment is carried out as a mechanical routine, the result is not only frequent failure, but, in many instances, the infliction of unnecessary, intense, and prolonged suffering. Dentistry is, in fact, no more a mechanical art than surgery. The practice of each, it is true, consists to a great extent of the application of mechanical apparatus, and of the use of cutting, sawing, and gouging instruments. But besides manual dexterity in the use of his tools, the surgeon is required to possess an adequate knowledge of anatomy, physiology, and pathology, the sciences upon which his art is based, for it is found that if he be without such knowledge his mechanical operations must prove commonly unsuccessful, and in many cases disastrous. Of the dental surgeon similar acquirements are demanded. Without them, even in what at first sight appear to be simple mechanical details of practice, he also—having in every case to deal more or less with living structures—must be liable to many errors, and his treatment must constantly fall short of success, if indeed, it do not aggravate the very mischief for which a remedy was sought. Mr. Tomes, than whom no scientific authority ranks higher, speaking of one of the commonest of dental operations, says—"There is, perhaps, no other operation performed upon the human body which is attended by the same unqualified success as that of filling teeth, for we not only succeed, in the great majority of cases, in arresting the further progress of disease, but we also replace the part which has been lost by an imperishable material, and render the organ as useful as it was prior to its becoming the subject of caries." How many, however, from personal experience can testify to the agony necessitating the instant extraction of a useful tooth which has been produced by the pressure of an improperly inserted stopping upon an exposed and inflamed nerve? With respect to still more purely mechanical processes, such as the application of artificial teeth and of instruments for the cure of the irregularities of the teeth, every dental surgeon meets daily with cases which originally could have presented no difficulty, but which, having been treated without regard to the physiology of the teeth and of the parts influenced by the apparatus, have resulted in discomfort, injury, and failure. Instances of this character might be multiplied to any length by an examination of the pathology of dental diseases and of the principles of dental mechanics. Such an examination renders it clear that in dentistry, as in every other department of surgery, ignorance being very closely allied to cruelty, cannot, under any circumstances, be tolerated, and it demonstrates the truth of the statement made some time ago, by the Editor of the *Lancet*, "That quack dentists are only one degree less injurious than quack doctors, because their power is more limited."

The course of study through which candidates for the licence in dental surgery of the College of Surgeons have to pass before admission to examination will serve to indicate the acquirements which the heads of the profession consider indispensable on the part of those who would practise in any department of dentistry. This curriculum, besides theoretical and practical instruction in dental surgery and mechanics, provides that the candidate shall go through a course of instruction in anatomy and physiology, medicine and surgery, and the collateral sciences, such as chemistry and materia medica, so that, having a due acquaintance with the nature of disease, and with the general principles of medical practice, he may avoid error, and be able to deal with confidence and success with the affections of that special region to which his practice will be confined.

None of the facts which I have adduced with regard to the professional knowledge necessary on the part of dental practitioners are denied, even by the quacks themselves, who, on the contrary, by the addition to their names of letters closely resembling the initials of a recognised degree, and by the use of artfully worded language in their advertisements, endeavour to lead the public to believe that they have undergone a professional education and possess a legal qualification. As an instance, the letters M.C.D.E. will occasionally be found tacked on to the name of a quack dentist. These letters, if they mean anything, signify Member of the College of Dentists of England, and they may be safely used whether a diploma be held or not, for the reason that that institution, which never had any legal status, terminated its career more than ten years ago after a very brief existence. With the same object, cunningly selected extracts from medical papers are made to appear as though they referred to the advertiser, whilst it is needless to state the editor had intended them to have no such application. An example of this latter expedient has been continually noticeable since the introduction of nitrous oxide gas as an anæsthetic in dentistry. Several of these men claim—of course falsely—to have been the original introducers of the gas, or to be specially skilled in its administration; and in order to render these claims more plausible, and at the same time to pretend that they have been recognised by the highest medical authorities, they publish in their advertisements extracts from articles in the medical papers, which had, in fact, simply discussed in general terms the properties of the gas and the method of its administration, and had perhaps contained no allusion to any individual. The same expedient is employed on every occasion when an improvement in treatment is made known, or when a new material or apparatus for mechanical operations is devised. Each quack endeavours in his advertisements to make it appear that he is the patentee of the new invention, or at least that he alone has the requisite skill and knowledge properly to apply it in practice.

It cannot however, be necessary to continue the subject further, and to expose in detail this system of chicanery and deception, which, indeed, in its main features, is identical with that carried on by every species of quack. I have said enough to justify the statements with which I set out. It must be evident that the evils which I have mentioned do really arise, from the admission into newspapers of dental puffs, under the mask of sham editorial articles. The public, driven as they must surely be, by powerful editorial influence, into the hands of the lowest members of the profession, are often made to suffer, not only loss of money, but unnecessary disappointment, pain, and injury to health; and as a result of this, a large body of honourable professional men, the legally qualified dental surgeons, frequently find themselves, much to their sorrow, classed by the indiscriminating public among the most ignorant and disreputable of charlatans.

I remain, Sir,
Your obedient servant,
HENRY SEWILL, M.R.C.S., L.D.S.,
Dentist to the West London Hospital, &c.

Daily News Office, London, January 12, 1876.

The manager of the *Daily News* presents his compliments, and begs to thank Mr. Sewill for the information he has given, and to add that the advertisement referred to was inserted without proper supervision.

HOUSE FOUNDATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with pleasure your remarks in this week's issue on the subject of "House Foundations." I called attention to the same subject last year through the columns of the *Daily Telegraph*, mentioning one case that came under my own observation in which human remains were used to fill up a pit from which the clay had been taken. Where the remains came from of course I could not tell; but there were several skulls, thigh-bones, &c., and any quantity of ribs, phalanges of upper and lower extremities, teeth, &c. The letter appeared during the "silly season," and did not seem to have attracted notice, owing possibly to its having been published in the supplement, which few people look at.

I am, Sir, yours obediently,
W. T. GREENE, M.B., M.A., &c.

218 Old Kent Road, S.E.

Literature.

LECTURES ON DERMATOLOGY. (a)

SESSION 1874-5.

THIS work consists of a series of discourses on Dermatology which are being delivered at the Royal College of Sur-

(a) "Lectures on Dermatology," delivered in the Royal College of Surgeons of England in 1874-1875; including Struma, Lupus, Lymphadenoma, &c., &c. By Erasmus Wilson, F.R.S., F.R.C.S., &c. London: J. and A. Churchill. 1875.

geons. They were commenced in 1870, and have now reached thirty-six in number. The former lectures were published in two volumes, in 1871 and 1873, and the present volume, which does not complete the series, contains the twelve lectures that have been recently delivered.

The plan of these lectures, observes the author, is to treat consecutively of the whole of the diseases of the skin, beginning with diseases of inflammation, common and specific, then taking diseases due to aberration of nutrition and sensation, and proceeding onwards to disorders of pigmentation, diseases of the epidermis and nails, of the cutaneous glandular system, and of the hair; and, further, a special object Mr. Wilson had in view was "to afford the opportunity of comparing the description of the disease with the object itself as preserved in the Hunterian Museum, to challenge inquiry, and to confirm or refute theory and preconceived conviction by an appeal to facts." The more important skin diseases treated of in the present volume are struma, lupus, epithelioma, ichthyosis, scleriasis, anglioma, spargosis, cheloma, besides which there is, at the beginning of the work, a description of the models added to the dermatological collection since the former course, and an account of the treatment of elephantiasis Græcorum with gurjun balsam or wood-oil. With respect to the efficacy of this medicine in the treatment of that loathsome and hitherto intractable disease, Mr. Wilson is very sanguine. He enters very fully into the medical history, nature, and properties of the balsam, and cites several cases in which it appears to have been of great service. The facts which the author has adduced, and which, in his opinion, are both extraordinary and encouraging, are founded on a report by Dr. Dougall, Surgeon-Major of the Madras Medical Service, to whom is due the merit of having introduced this remedy. The balsam is used internally and in the form of an ointment, and it appears to be especially efficacious in the anæsthetic variety of leprosy. "It is pleasing," writes Dr. Dougall, "to see the will with which men who for years had not been able to handle a walking-stick, on account of loss of fingers and numbness in the arms, now set about this sort of work (rubbing themselves with the ointment), and they are evidently proud of being again able to work, when such a hope had been abandoned long ago." In fact, judging from the evidence of others, and from his own experience, Mr. Wilson acknowledges that the success of the gurjun treatment has been very extraordinary, and remarks that he has also found it very useful in the treatment of chronic eczema, lupus vulgaris, and lepra Græcorum. After a very good description of strumous disease of the skin, in which the reader is referred, according to the plan of the work, to several models illustrative of the several stages and form of scrofuloderma, we pass on to lupus, lymphadenoma, (lymphoma), xanthoma, and epithelioma, affections which, along with struma and lepra vulgaris, are classed under the "dystrophic affections." "In grouping together common strumous inflammation of the skin and lupus, I have," says the author, "been chiefly influenced by the pathological conditions of the skin in advanced stages of these two affections, the difference between them being by no means greater than we see evinced by the various forms of cutaneous disorder manifested by syphilis. . . . ."

The second half of the volume is taken up with the lectures that were delivered during the current year. In these we have a description of ichthyosis, sauriosis (sauroderma), striæ atrophicæ, morphœa, scleriasis (scleroderma) among the "atrophic affections;" of spilus, verruca, cornua, clavus, angeoma, neuroma, and fibroma, among the hypertrophic affections; of spargosis (elephantiasis Arabum), molluscum, and cheloma among the fibromata; and lastly, of pruritus, prurigo, neurotic excoriations, dermatalgia, hyperæsthesia, and anæsthesia among the neuropathic affections.

At the end of the volume there is an interesting account of hæmorrhagic neuropathic excoriations, and of bleeding stigmata, and two or three remarkable examples of the latter affection are given. In reference to these "bleeding stigmata," which, Mr. Wilson observes, is pathologically made up of "capillary congestion, serous exudation, and hæmorrhage" of the hyperæmic corium, and which may be imitated by applying in a particular manner a piece of blistering-tissue to the skin, reference is made to the remarkable case of Anne Louise Lateau. This is a striking example of the same affection, associated with hysterical and ecstatic phenomena. After giving an account of the case as related by Dr. Lefebure, of Louvain, the author says: "In this remarkable case of neuropathic disorder, accompanied with vesication of the skin and hæmorrhage, we perceive a curious resemblance to the cases of 'neuropathic excoriations' which I have just been describing—a resemblance which is, indeed, pathologically identical, and only differs in the striking character of its periodical recurrence—a feature by no means strange to physiology and pathology." Not the least valuable part of these lectures is the description of the treatment adopted by the author, and as any opinions on this subject from a surgeon of Mr. Wilson's experience cannot fail to attract our attention, we will briefly mention a few points in his practice most worthy of notice. In the general treatment of *struma* the author endorses the opinion of the profession as to the great value of cod-liver oil, iron, iodine, and other well-known antistrumous remedies. But when struma presents itself in the form of a local phlegmon, threatening to become an abscess, "the most successful treatment" consists in covering the affected part with a plaster of opium and galbanum spread on washleather. Under this treatment the phlegmon will probably disperse without suppuration, or the glands will recover without softening and ulceration. The plaster should be renewed if required, and if suppuration be inevitable it will be well to make two or three slashes in the centre of the plaster to let the discharge find its way out at its will. Among the caustics used in the local treatment of *lupus vulgaris*, Mr. Wilson speaks from a long experience of the value of the potassa fusa, which he uses in the form of a solution (equal parts of the caustic and distilled water), and the same caustic—of the same strength—he uses in the treatment of *epithelioma*. "I believe," he says, "the potassa fusa to be superior to all other chemical remedies, and especially so for the rapidity of its operation, the moderate pain it occasions, and the rapidity with which that pain ceases entirely." For the therapeutic treatment of *dermatoxerasia*, *ichthyosis*, and *sauriosis*, the author insists upon nutritious diet, attention to the general health, and the liberal use of fatty inunctions and saponaceous ablutions. Arsenic, quinine, iron, and other tonics, with saponaceous ablutions and moderate local stimulations, are the best remedies for morphœa, striæ atrophicæ, and scleriasis.

In conclusion we may observe that this work, in connection with the valuable pathological models which it illustrates, will be, when completed, a very important and a very handsome addition to the literature and pathology of cutaneous medicine. At the same time, and although these volumes are—as respects type, quality of paper, and binding—got up in a most sumptuous manner, we cannot recommend them as a good text-book for students. Many pages are devoted to long clinical reports. Constant reference is made to the models, of which many portions of the work may be said to form a sort of scientific catalogue, and the study of which is supposed to go hand in hand with that of the book itself; and, finally, the causes, symptoms, diagnosis, and treatment of skin diseases are not always so fully described as they would be in an ordinary compilation or text-book.

Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Members of the College on January 27th :—

Robert Bridges, M.B. Oxford, St. Bartholomew's Hospital, E.C.

Francis Henry Champneys, M.B. Oxford, 4 Oak Hill Park, N.W.

David White Finlay, M.D. Glasgow, Middlesex Hosp., W.

William McNeill Whistler, M.D. Pennsylvania, 80A Brook Street, W.

Albert John Venn, M.D. Aberdeen, 30 New Cavendish Street, W.

Robert Mundy Gover, Millbank Prison, S.W.

Royal College of Surgeons of England—The following gentlemen, having passed the required examinations for the diploma, were admitted to the Membership of the College at meetings of the Court of Examiners on January 24th, 25th, 26th, 27th, and 28th :—

Allott, Wordsworth Leach, Leeds.

Bark, John, L.K.Q.C.P.I., Great Crosby, Lancashire.

Betty, Samuel G., L.S.A., Park Street, London, N.W.

Boys, Arthur Henry, Brixton Hill, Surrey.

Braithwaite, Samuel, Egremont.
Burton, Samuel Herbert, Great Yarmouth.
Chadwick, George Richard, L.S.A., King's Lynn.
Champneys, Henry L., New Street, E.
Coffyn, Stephen, Silverdale, Sussex.
Cooper, John N., L.K.Q.C.P., Hyde, near Manchester.
Cameron, Charles H. H., Plymouth.
Davis, Henry, L.S.A., Euston Square.
Duke Edgar, Clapham Road.
Eccles, Robert, Larne, Co. Antrim.
Ellis, William Aston, Pimlico.
Evans, Charles W., Bakewell.
Evans, Frederick W., L.S.A., Cardiff, S. Wales.
Fendick, W. Rowing, L.K.Q.C.P.I., Bristol.
Finch, Alfred, Blackheath.
Fitzgerald, James G., Cambridge Street.
Forrest, John G. S., Bessborough Gardens.
Fox, Thomas Colcott, Broughton, Hampshire.
Francis, Ernest G., Sutton.
Gardner, John Arthur, Northallerton, Yorks.
Gorst, Henry, Huyton, Lancashire.
Grimwood, Harry Charles, L.S.A., Stowmarket, Suffolk.
Grimbly, Richard H., Banbury, Oxon.
Harris, Stanford, L.S.A., Pendlebury, Manchester.
Hay, John Horne, Wandsworth, Surrey.
Hayes, Thomas George, West Brompton.
Holwell, Edward B., Leeds.
Jackson, Arthur A., Adbaston, Newport.
Jacob, Ernest Henry, M.B. Oxon., Winchester.
James, Walter C., L.S.A., Kennington-park Road.
Jones, Abraham Emrys, Manchester.
Kanoba Rauchhoddas, Kirtikar, Bombay.
Layborn, William K., Beverley.
McCarthy, George F., Dublin.
Mackern, George, Blackheath.
McLarty, C., M.B. Toronto, St. Thomas's, Ontario.
M'Carthy, Justin M'Callum, St. Thomas Terrace.
M'Cullagh, Thomas Alexander, Liverpool.
Millman, T., M.D. Toronto, Woodstock, Ontario.
Moone, John, Mornington Road.
Moorhead, James, M.D. Dub., Belfast.
Naylor, Charles G. R., L.R.C.P. Edin., Calcutta.
Nicholls, Frederick, Stockwell, Surrey.
Nicholson, J. F., Brigg, Lincolnshire.
Oram, Richard R. W., Stonehouse, Devon.
Osborne, John Henry, L.S.A., Southwell, Notts.
Paxon, Herbert E., L.S.A., Dorking.
Paget, Edward, Thurstan, Guernsey.
Pearless, Walter Relf, East Grinstead, Sussex.
Perry, Edward Verdon, Reepham, Norfolk.
Pickburn, T. J., M.B. Aberd., Sydney, Australia.
Pickup, William James, Bacup, Lancashire.
Popert, Adolp J., L.S.A., Limehouse, E.
Price, Robert John, University Street, W.C.
Prouger, Charles Ernest, Crawley, Sussex.
Richmond, C. E., L.S.A., Manchester Royal Infirmary.
Roberts, William S. W., Earls Court Road.
Rockliffe, William Craven, L.S.A., Hull.
Rogers, Thomas King, Hackney.
Russell, James, M.B. Aberd., Croydon, Surrey.
Ryley, James, Louth, Lincolnshire.
Sandes, Walter H. F., Wandworth, Surrey.
Saunders, Edward A., L.S.A., Haverfordwest.
Scott, John William, Dronfield, Yorkshire.
Sellon, J. W. Gore, Budleigh Salterton, Devon.
Shoolbred, William Andrew, Wolverhampton.
Speed, Henry Andrews, Lewisham, Kent.
Startin, James, Kennington Road.
Stewart, William Robert, Russell Street, E.
Stephenson, William Arnold, Weymouth.
Strange, Orlando B., Hammersmith.
Taunton, William W., Salisbury, Wilts.
Wade, Arthur Breedon, Ryde, Isle of Wight.
Walford, Robert, Colchester.
Walker, George A., M.B. Aberd., Darlington.
Wartenberg, Victor A., Lytham, Lancashire.
Weddall, William, L.S.A., Stamford.
Whitelegge, Benjamin A., Tideswell, Derbyshire.
Wise, Alfred T. T., Warlock Road.
Wolff, Alfred Abraham, Gloucester Gardens, W.
Wood, Edwin Stanley, Newport, Monmouthshire.
Wright, William H., L.S.A., Derby.
Wright, Henry, Lutterworth.

Vital Statistics.—From the Registrar-General's returns we learn that during last week 6,007 births and 4,342 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 28 deaths annually in every 1,000 persons living. The annual death-rate was 27 per 1,000 in London, 23 per 1,000 in Edinburgh, 30 in Glasgow, and 34 in Dublin. The annual rates of mortality per 1,000 during the same period in the other large towns were—Brighton 16, Sunderland 21, Plymouth 25, Norwich 28, Nottingham 33, Bradford 25, Hull 27, Leicester 21, Bristol 35, Portsmouth 16, Sheffield 29, Birmingham 29, Wolverhampton 24, Leeds 24, Newcastle-on-Tyne 23, Oldham 45, Liverpool 36, Manchester 36, and Salford 45. The annual death-rate from the seven principal zymotic diseases averaged 4·0 per 1000 in these towns, and ranged from 0·0 and 0·7 in Brighton and Plymouth, to 7·9 and 9·4 in Salford and Oldham. Three fatal cases of small-pox occurred in Manchester and Salford, and 2 in Bristol. Scarlet fever showed fatal prevalence in Oldham, Bradford, Bristol, and Salford. Fever caused 8 more deaths in Sheffield. In London, the 1,782 deaths included 60 from scarlet fever, 20 from different forms of fever, 16 from diarrhœa, and not one from small-pox; 250 deaths were referred to the seven principal diseases of the zymotic class, against 265 and 239 in the two preceding weeks, being 18 below the corrected average.

Liverpool Medical Institute.—The following office bearers were elected at the annual meeting in January:—*President.*—James Turnbull, M.D., F.R.C.P. *Vice-Presidents.*—Dr. Steele, Mr. Charles B. Wilson, Dr. Glynn, Mr. Higginson. *Treasurer.*—Dr. Oxley. *Hon. Secretary.*—Dr. Lyster. *Hon. Sec. of Ordinary Meetings.*—Mr. Chauncy Puzey. *Hon. Librarian.*—Dr. William Carter. *Members of Council.*—Drs. Bligh, Campbell, Dickinson, Grimsdale, Waters, Adam, Armstrong, J. Cameron, Parsons, Pollard, Rawdon, and Mr. George H. Snape. *Microscopical Committee.*—Drs. Davidson, Braidwood, Wm. Carter, Caton, Glynn, Lupton, Mr. Newton, and Mr. Rushton Parker. *Auditors.*—Drs. Bailey and Glynn.

Gallic Acid in the Treatment of Albuminuria.

THE following is from an article by J. T. Jameson, M.D., in the *American Practitioner*:—

I wish to call attention to the use of gallic acid in the treatment of albuminuria as a sequel to scarlet fever, with which, in a few cases, I have met with marked success. My experience with the remedy has been as follows:—

In my first case, occurring in a boy aged about twelve years, the symptoms were very severe. There was œdema of the face and lower extremities, but no effusion into the thoracic or abdominal cavities; violent headache; blindness; there had been four or five strong epileptiform convulsions; urine was scanty and contained blood, resembling exactly water in which fresh beef had been washed, and coagulating about one-half on testing with heat and nitric acid. To relieve the cerebral symptoms, a blister was applied to the neck, sinapisms to the extremities and lumbar region, cold to the head, and two or three doses of a mercurial with bitartrate of potassa. This was followed by iodide of potassium and a teaspoonful of a saturated solution of gallic acid every two hours. The acid was given in this manner for five days and nights in succession, the patient rapidly improving under its use, and the urine becoming more copious and less bloody. It was continued for twenty-two days, only at longer intervals, and at that date the urine when tested manifested the slightest possible trace of albumen, although the boy at this time was around the house and apparently perfectly recovered, having been so for a number of days. The tinct. ferri chloridi was given in small doses, and completed the cure.

My second case occured in a girl about six years of age. The eruption was very livid and the skin had desquamated. The child recovered well from the fever, and was about the house. She went into a cold room to play with other children, and a day or two after the face became œdematous; there was pain in the head; slight fever; urine quite bloody, and on testing in the usual manner presented considerable coagulation. The patient was put upon a saturated solution of gallic acid, a teaspoonful every two hours. In seven days the urine was free from albumen and copious in quantity, and the child seemed well, with the exception of debility, for which the muriated tincture of iron was prescribed. About ten days after this, in consequence of fresh exposure to cold, there was

a slight relapse, the urine becoming again bloody and the face puffed; but on resuming the gallic acid for a few days these symptoms speedily subsided and the recovery became permanent. In this case the gallic acid was administered unaccompanied by any other medicine, except an occasional dose of castor-oil to regulate the action of the bowels.

Remarks.—The treatment hitherto generally adopted in this affection has been that of acting derivatively on the bowels by means of mercurials, followed by such diuretics as digitalis, sweet spirits of nitre, acetate of potash, etc.; but if future experience should confirm the efficiency of gallic acid, I cannot but think we shall possess a remedy superior to any of the above. The gallic acid if I understand its action aright, enters the blood unchanged, and unchanged is carried directly to the congested and inflamed capillaries of the secernent portion of the kidneys, acting as an astringent and tonic upon them, promoting their contraction, and thus arresting the exudation of red blood corpuscles and promoting the normal secretion of urine. I have seen no unpleasant effects from its administration as freely as above represented. It does not disturb the stomach nor interfere with the appetite or digestion, but it does tend to constipate the bowels somewhat, rendering necessary the occasional use of a relaxative.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A correspondent has sent for publication some suggestions and comparisons between the British and Indian Medical Departments. Our correspondent has not furnished us with his name, not necessarily for publication, but in compliance with our rule.

Dr. Abrath, of Sunderland, has forwarded to us the correspondence which has resulted between him and the Editor of the *Students' Journal* relative to a lecture delivered by Dr. Abrath "On the Work done under the Red Cross," which the editor of that journal characterised as a burlesque. Dr. Abrath was not unnaturally indignant at such an expression, and wrote a long letter in self-defence. As the editor inserted this production, albeit at times wide of the subject of complaint, there is no necessity for us, nor indeed have we space, to transfer it to our columns. We believe in the sincerity of Dr. Abrath's intentions, but the exceptional and extraordinary way he carries those intentions into operation will always invite attack. It may be German; it certainly is not, and we trust never will be, English.

Dr. J. W. Lane, Bishops-Castle, forwards us a specimen of the trash a quack is distributing in and about the neighbourhood of Hereford. Prof. Owens—the title this worthy adopts—having previously left his printed sheet of bunkum, on which he notifies that when he calls again he will give advice gratis on a specified host of diseases, repeated his visit to our correspondent, Dr. Lane. Being out at the time, the Professor inquired of the servant if his circular had been shown to her master, as he was certain he would give a good sum to know his remedies!! Dr. Lane regrets that he was not at home in order to have considerably expedited the fellow's exit, and is naturally indignant that there is no protection for the profession or the public from these impostors. We sympathise with our correspondent, but would suggest that, as the law guards these worthies from summary punishment, he should not give vent to his just indignation by soiling the toe of his boot, albeit that it would be thoroughly merited.

Vaccine Items.—Apropos of the anti-vaccination war which appears to be again breaking out in various parts of Christendom, newspaper writers are indulging in a little chaff. The following are specimens: A rural physician, on receiving a sample lot of animal virus on quills, supposed them to be toothpicks, and employed them accordingly. During the discussion on vaccination in the Cincinnati Academy of Medicine a week or two since, Dr. Muscroft stated that a druggist of that city who deals in vaccine crusts, had some returned to him recently with a letter from the physician stating that he had tried it, and it had failed in every instance. On examination, it was found that he had merely chipped off a small amount of the wax covering, but had not even reached the tin-foil surrounding the crusts. Another doctor boils his quill points thoroughly before using them, and then thinks "they are not so reliable as crusts taken from healthy children."

The Army Medical Service.—For some unexplained reason the examination of candidates for admission to vacancies in this branch of Her Majesty's Service, announced for the 14th inst., has been countermanded. Is it because no candidates have sent in their names? Perhaps the authorities will at last see the necessity of making the medical department a little more attractive.

Communications, Enclosures, &c., have been received from—Mr. Squire, London. Dr. Dobell, London. Dr. Thorowgood, London. Dr. Frederic Hall, Wragley. Dr. Althaus, London. Dr. Campbell Black, Glasgow. Dr. Collins McElroy, Zanesville, Ohio. Mr. Bruce, London. Dr. Gordon, Madras. Mr. Gray, London. Mr. T. Parker, London. Dr. Drysdale, London. Mr. Swanzy, Dublin. Dr. Hughlings Jackson, London. Dr. Barton, Dublin. Mr. Nolan, Castleisland. Mr. Martin, Portlaw. Dr. Hardwicke, London. Mr. Haviland, Northampton. Mr. Crawford, Edinburgh. Dr. McNaughton Jones, Cork. The Secretary to the India Board. Dr. Greene, Kent Road. Dr. J. G. Thornley, Leicester County Asylum. Mr. Sewill, London. Mr. Verdon, London. The Registrar of the Royal College of Physicians of London. The Secretary of the Liverpool Medical Institute. Dr. Abrath, Sunderland. Dr. Knox, Strandtown. Dr. Godfrey, Dripsey. Dr. O'Grady, Dublin. Dr. Lindsay, Belfast. Dr. Dobbin, Keady. Dr. Seymour, Baltinglass. Dr. Furlong, Srteamville. Dr. Rice, Galway. Dr. Sandiford, Castlemartyr. Dr. Love, Killygordon. Dr. Higgins, Cheltenham. Dr. Lane, Bishops-Castle, &c., &c.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

On the Development of the Ova in Man and other Mammalia. By James Foulis, M.D. Edinburgh.

Fifth Annual Report of the Metropolitan Imbecile Asylum at Caterham.

Evolution of the Human Race from Apes. By T. W. Jones, F.R.S.

The late Visitation of Typhoid Fever at Uppingham. Statement of the Sanitary Committee and Messrs. Haviland and Field.

Electro-Therapeutics. By Collins McElroy, M.D., Zanesville, Ohio.

Medical Responsibility in the Choice of Anæsthetics. By H. M. Jones, M.D. London: Lewis.

Eleventh Annual Report of the Sanitary Commissioner with the Government of India.

Canada Medical Journal. La France Médicale. Le Progrès Médical. British Journal of Dental Science. La Tribune Médicale. Boston Medical Journal. Glasgow Medical Journal. Journal d'Hygiène. The Clinic. Australian Medical Journal. New York Medical Journal.

VACANCIES.

Royal Hospital for Diseases of the Chest, City Road.—Surgeon. Honorary. (See Advt.)

North London Consumption Hospital.—Physician. Honorary. (See Advt.)

Queen's College, Galway.—Professorship of Midwifery. Testimonials to the Under Secretary, Dublin Castle. (See Advt.)

London Hospital.—Assistant Obstetric Physician. Full particulars of the Secretary.

Birmingham General Dispensary.—Resident Surgeon. Salary commencing at £130 per annum. Applications to the Secretary.

Stratton Union, Cornwall.—Medical Officer for the South District of the Union. Salary, £60, with extras. Applications to the Clerk of the Board of Guardians.

Manchester Clinical Hospital for Children.—House Surgeon. Salary, £80 per annum. Address the Secretary of the Medical Board.

North Witchford Union, Cambridgeshire.—Medical Officer for the East Division. Salary, £60, with fees extra. Applications to the Clerk of the Board.

Kent County Lunatic Asylum.—Medical Superintendent and an Assistant Medical Officer. Salary of the former £700, with house; of the latter, £150, with apartments. Applications by letter to Messrs. Beale and Hoar, Maidstone, Kent.

APPOINTMENTS.

Benton, S., L.R.C.P.L., M.R.C.S.E., L.M., Assistant Medical Officer to the Central London Sick Asylum District at Highgate.

Burgess, E. J., M.R.C.S.E., L.R.C.P.L., Midwifery Assistant to St. Bartholomew's Hospital.

Coldstream, A. R., M.B., C.M., L.R.C.S.Ed., a Resident Physician to the Royal Infirmary, Edinburgh.

Crabb, J., M.B., C.M., a Resident Surgeon to the Royal Infirmary, Edinburgh.

Garson, J. G., M.B., L.R.C.S.Ed., a Resident Physician to the Royal Infirmary, Edinburgh.

Godfrey, C. W., M.R.C.S., House Surgeon to the Huntingdon County Hospital.

Grange, W. D'O., M.B., C.M., a Resident Surgeon to the Royal Infirmary, Edinburgh.

Greenway, A. S., M.B., a Resident Medical Officer to the St. Mary's Hospital for Women and Children, Manchester.

MacDonald, T. R., L.R.C.S.Ed., a House Surgeon to the Royal Infirmary, Edinburgh.

MacLeod, N., M.B., C.M., a Resident Physician to the Royal Infirmary, Edinburgh.

Newington, A. S. L., M.B., M.R.C.S.E., Medical Officer for the Waterperry District of the Thame Union, Oxfordshire.

Prideaux, Mr. E., Assistant House Surgeon to the Derbyshire General Infirmary, Derby.

Purefoy, R. D., M.B., Obstetric Physician to the Adelaide Hospital, Dublin.

Roy, C. S., M.B., C.M., a Resident Physician to the Royal Infirmary, Edinburgh.

Scott, C., L.R.C.S.Ed., Medical Officer and Public Vaccinator for the Bagnal-town Dispensary District of the Carlow Union.

Spence, T. F. H., M.B., C.M., a Resident Surgeon to the Royal Infirmary, Edinburgh.

Vause, A. J., M.B., C.M., a Resident Physician to the Royal Infirmary, Edinburgh.

White, C., M.R.C.S.E., Consulting Surgeon to the Warrington Infirmary.

Marriage.

Haynes—Hiron.—On the 27th ult., at St. George's, Hanover Square, London, Fredk. Harry Haynes, M.D., of Leamington, to Henrietta, youngest daughter of the late John Hiron, Esq., J.P., of Campden, Gloucestershire.

Deaths.

Burleigh.—On the 15th Jan., at Torquay, Alfred Burleigh, M.R.C.S.E. of Hillside, Cotham, Bristol.

Clark.—On the 23rd Jan., at Inverness, Hugh Clark, M.D., aged 40.

Cooke.—On the 14th Jan., at Hagley-Hay House, Walsall, J. L. Cooke M.R.C.S.E., aged 30.

FLEWKER.—On the 16th Jan., at Albury, Surrey, Wm. Flewker, Surgeon, aged 70.
MARSHALL.—On the 12th Jan., at Bucklyvie, Stirlingshire, James Marshall, L.R.C.S.Ed., aged 48.
MITCHELL.—On the 12th Jan., at Stonehouse, Lanarkshire, James Mitchell, M.D., aged 79.
PARKER.—On the 5th Jan., at Eversholt, Beds, Thos. Parker, Surgeon, aged 78.
WETHERFIELD.—On the 25th Jan., at Croom's Hill, Greenwich Park, John Wetherfield, M.R.C.S.E., formerly of Henrietta Street, Covent Garden, aged 76.
WILSON.—On the 21st Jan., at his residence, Brookeboro', co. Fermanagh, John Wilson, M.D., aged 46.
WORTS.—On the 20th Jan., at Colchester, Wm. Worts, M.R.C.S.E., aged 75.

TO THE PROFESSION.

IRISH PHARMACY ACT.

THE above Act having now come into operation,

J. T. HOLMES,

PHARMACEUTICAL CHEMIST

(Member of the Pharmaceutical Society of Great Britain, and Member of the Irish Pharmaceutical Council),

THE PEMBROKE PHARMACY,

30 UPPER BAGGOT STREET, DUBLIN,

solicits the patronage of the Profession.

None but Drugs and Chemicals of guaranteed purity.

All the preparations of the Pharmacopœia made strictly according to formulæ.

Foreign Natural Waters of every kind—Apollinaris, Friedrichshall, Pullna, Seltzer, Vichy, &c., &c.

Special Agent for Thwaites' Mineral Waters, and Mr. Eskell's Dentocrete, and other preparations.

XMAS ACCOUNTS

MERRITT and HATCHER send, post free, on application, a variety of Samples and Prices of MEDICAL BILL FORMS, by which a great saving of time in making out accounts is effected.

Merritt and Hatcher, Printers, 2 Grocer's Hall Court, Poultry, London, E.C.

BLANCARD'S IODIDE OF IRON PILLS.

APPROVED BY THE ACADEMY OF MEDICINE OF PARIS.

Partaking of the properties of *Iron* and *Iodine*, BLANCARD'S PILLS are especially suited to act against the numerous affections determined by Scrofulous Cachexia, Amenorrhœa, Dysmenorrhœa, Chlorosis, Anæmia, and the first stages of Phthisis. By stimulating the organism, they gradually fortify weak, debilitated, and lymphatic constitutions.

N.B.—None are genuine unless signed Blancard, Chemist, 40, Rue Bonaparte, Paris.

Blancard

Pharmacien, Rue Bonaparte, 40, Paris.

Wholesale in London, G. JOZEAU, the only French Chemist of the first class received by the Paris School of Pharmacy, 49 Haymarket, W.; and F. NEWBERY and SONS, 37 Newgate Street, E.C.

"SWEET" ESSENCE OF RENNET.

TRACHEOTOMY IN CROUP. (a)

By Wm. Thomson, A.B., M.D.,

Fellow and Member of the Surgical Court of Examiners, Royal College of Surgeons, Ireland; Surgeon to the Richmond Surgical Hospital, &c.

I wish to bring before the Society this evening a subject that is not new, but my apology must be its importance and a desire to elicit discussion regarding it. Croup and its treatment form one of the most difficult questions in surgery, and it is to this latter that I desire to ask the attention of the members for a short time. I will first give the notes of some cases that have come under my own notice, and then append such general observations as may appear to bear upon them.

Case 1.—On Sunday evening, 16th August, 1874, John Carr, æt. 5, was admitted to the Hardwicke Hospital, under the care of my colleague, Dr. Gordon. He was a healthy-looking, chubby, fair-haired, blue-eyed boy, and had been reared at Howth. Three days before his admission he had become unwell, and had gradually grown worse until he was brought into town. He was seen by Dr. Gordon immediately, and was pronounced to be suffering from well-marked croup. There was no pharyngitis, no sign of any membrane about the tonsils or pharynx, but the croupous inspiration and cough were well marked and unmistakable. His mother stated a fact of much interest—that his sister had been admitted to Sir Patrick Dun's Hospital a week before with diphtheria, from which, as I afterwards learned, she recovered. On his admission to hospital he was put to bed, rolled in warm blankets, and had linseed-meal poultices applied to the throat at frequent intervals, while he was ordered to have a mixture containing squills and ipecacuanha. He passed an uneasy night, the breathing being rapid and the pulse high. Towards morning the symptoms became more urgent, and at times he seemed to be almost asphyxiated. At half-past ten he was seen by Dr. Gordon and Dr. Gerald Yeo. He appeared to be dying. His extremities were cold, his face was pallid and puffed, the breathing was very difficult, and there were general indications of collapse. An examination showed that air was entering his lungs, and there was fair resonance. A blanket steeped in hot water and mustard was wrapped round his body, and he rallied sufficiently to be able to recognise his parents; but Dr. Gordon saw that the case was hopeless unless surgically relieved, and he accordingly at once sent for the late Mr. Hamilton, who happened to be the surgeon on duty. In a few minutes all the surgeons—Mr. Hamilton, Mr. Stokes, Mr. Thornley Stoker, and myself—were at the patient's bedside, where we had the advantage of consulting with Drs. Banks, M'Dowel, Gordon, and Lyons. The child was at that time almost moribund. He lay upon the bed making feeble efforts to get breath, his face blanched and bathed in cold sweat, his lips quite blue. There was no hesitancy upon the part of any one as to the propriety of an operation. The child was plainly dying of apnœa, and the immediate indication was to relieve that condition. Mr. Hamilton asked me to undertake the operation. The child was at once moved to the end of the bed, and with the assistance of Mr. Stokes and my other colleagues the trachea was opened. It was the first time that I had performed the operation, and it was very forcibly impressed upon me that it is not an easy one. Before an opening was made the child appeared to be dead, and it was not altogether cheering to be assured that that event had actually occurred. But the opening into the trachea (involving the 1st, 2nd, and 3rd rings) and the introduction of the tube was followed by a fit of coughing which gave us hope. A quantity of thick yellowish shreddy material was ejected through the tube. For several minutes, however, it was necessary to continue means of resuscitation, and at las

(a) Communicated to the Surgical Society of Ireland on the 21st of January, 1876. The discussion will be found at page 92.

we were rewarded by seeing consciousness restored. Within half an hour he was laughing, playing with a toy, and holding such intercourse with his parents as he was able.

He was removed to a small ward at once, where the temperature was kept rather high, and the steam from a kettle was allowed to escape close to his head. He was carefully nursed by Dr. Farrell (lately appointed Assist.-Physician to the Mater Misericordiæ Hospital), Mr. Mark M'Donnell, and Mr. Nixon. During the day the respirations were easy and greatly diminished in frequency; pulse 126. He was able to take nourishment without difficulty, although some milk came through the tube at first. His bowels were moved five times, the stools being of a light green colour.

Tuesday—Did not sleep well. About 8 a.m. had a sudden attack of dypsnœa. There was great lividity of countenance, but the obstacle was caused by a pellet of lymph, of the consistence and colour of crude honey, which blocked up the tube. This was removed and cleaned. At 2 o'clock the temperature was 103 deg.; pulse 140; respirations 50. Dr. Gordon saw him and ordered a mixture containing liq. ammoniæ acetatis and squills. The diarrhœa still continued; the stomach would not retain nourishment. At eight o'clock in the evening temperature was 105 deg.; pulse 170; respirations 55. From that time he gradually continued to sink, and died quietly at eleven o'clock, thirty-seven hours after the operation.

The post-mortem examination revealed the existence of a tough, false membrane throughout the track of the air-passages from the larynx down. It was of a very pale pink, easily separated from the mucous membrane, and about half a line in thickness. The interior of the larynx, with the vocal cords, were covered with it, and it could easily be traced to the smaller bronchial tubes. The lungs themselves contained some air, but were, generally speaking, œdematous. There was no trace of membrane extending beyond the larynx into the pharynx.

Case 2.—Michael Kelly, aged eighteen months, a plump and healthy-looking boy, although small for his age, was admitted to the Richmond Hospital at ten o'clock on Saturday morning, July 24, 1875, having been presented at the medical dispensary under Dr. Harvey's care. I saw the child half-an-hour afterwards. He was suffering from severe dyspnœa. He was, however, still strong, and tried to resist any effort to examine his chest, although I was able to satisfy myself that air was entering the lungs. The inspiratory sounds were strongly accentuated, but there was no cough. The face was pale. The mother said the child had had a cold for a week, and the symptoms had only become urgent the night before his admission. I afterwards learned, however, that she had not seen the child for a week. I had the little patient at once placed in a small ward, so that the temperature might be regulated. A constant jet of steam was discharged by means of a pipe in the neighbourhood of the patient's head, but sufficiently far not to be unpleasant. He was ordered to have a grain of calomel every hour until the bowels were moved, and a consultation was summoned for twelve o'clock. Owing to various circumstances none of my colleagues could come. On my return matters were much worse. The child was evidently dying. His lips were blue, his face pale, his eyes half-closed and dull, the pulse small and so rapid that it could not be counted, while he lay in bed gasping for air and throwing his arms about. I determined to operate at once, and having obtained the mother's consent I did so. I was very ably assisted by Dr. Stack, the resident surgeon, who throughout paid the most unremitting attention to the case; by Dr. S. Gordon, jun., and others. The operation was quickly performed. Having cleared everything from the trachea, I placed the forefinger of my left hand upon it, and using my nail as a guide, slipped the blade of a Paget's knife, held short by the thumb and finger of the right hand, between two rings above the isthmus, and divided the first, second, third, and fourth. There was no need to "plunge" the knife into the trachea. The word is a misleading one, and ought not to be used without some qualifying expression. The ordinary bivalve canula was then introduced. On making the opening a quantity of purulent sticky matter was shot through it with some force. Then there were a few feeble attempts at respiration, but these ceased and the child seemed about to die on the table. Dr. Stack immediately used the Sylvester method of artificial respiration; the body was flicked with a towel, water was sprinkled over the face, and wine poured down the throat, but all seemed equally unavailing. An ounce of wine was then injected into the rectum, and after some time the child began to revive. He was put to bed, rolled in warm blankets, and then gradually recovered. Before the operation the respirations were 54; afterwards they speedily fell to 30, the pulse to 148.

At the evening visit the change was remarkable. No one would have thought that he was otherwise than perfectly healthy. The nurse was feeding him with milk, and he took it with evident relish. His eyes were bright and intelligent. When the milk was withheld from him he managed to help himself. At four o'clock his temperature was 104°, pulse 160, respirations about 35.

The bowels having been moved three times before my arrival, the calomel was stopped, eight grains having been administered. With this exception the treatment was continued. Up to twelve o'clock all seemed favourable, but the child then began to sink, and died about two o'clock, convulsed.

The post-mortem examination showed great engorgement of the lungs. The glottis was almost blocked up with a pale tenacious membrane, which extended throughout the course of the trachea but not beyond it, the bronchi remaining free. In neither case was an anæsthetic used.

Case 3.—I was asked by Dr. Gordon some months ago to see a case of croup in which the expediency of interfering by operation had been considered. The patient was a delicate boy of about fourteen years of age, and had been suffering from the disease for some days before I saw him, having only recovered from a smart attack of pleuro-pneumonia. Shortly before our arrival he had expectorated a false membrane, forming an accurate mould of the trachea. When we entered the room he was sitting up in bed, leaning upon one hand, and making vain efforts to fill his lungs with air. I shall never forget the appealing look for help which he gave us. But auscultation and percussion proved that the lungs were almost airless, and the fact that the trachea had just been cleared without giving relief showed that the bronchi were blocked up, and that any surgical treatment would be unavailing. In an hour afterwards he was dead. No post-mortem examination was obtained in this case.

These cases are sufficient to illustrate different phases of the disease; and although in the two in which I operated when the child was dying, life was not saved, I do not think I am claiming too much when I regard them as strongly justifying surgical interference. The treatment of croup has followed two very distinct lines—that of medication and that of operative procedure. In the first have been included tartar emetic as a depressant, or to produce its specific action, mercury, blood-letting, alkaline salts, iron, and a great variety besides. The practitioner is in a state of almost hopeless perplexity when he comes to treat his first case of croup. He finds one authority pinning his faith strictly to tartar emetic, another to mercury, another condemning both these and contending that the surest reliance is to be placed on chlorate of potash and iron, or quinine. But there is one point upon which, until a comparatively recent period, there has been tolerable unanimity—viz., that tracheotomy is not to be entertained as a method of treatment except under circumstances which we now know give little chance of its being successful. A change, however, has been gradually

effected in respect of the propriety of this operation, and of late years the successes of French surgeons have compelled more attention to it in England, Scotland, and America. In Ireland, however, this is not so. The cases are very few in which the remedy has been applied, and I think it may fairly be stated that Irish practitioners are still ranged with the opponents of tracheotomy in croup or diphtheria. The discussions which have taken place in this Society from time to time, and more particularly upon a paper by my colleague, Mr. Corley, in 1870 (MEDICAL PRESS AND CIRCULAR, April 27, 1870), clearly indicate how general professional opinion stands in regard to it. The cause is not far to seek. We have a great respect for authority which is dignified by culture, boldness, and decision; and so we find that the teaching of a late distinguished professor of surgery of this College, Mr. W. H. Porter, still influences surgeons against the undertaking. Mr. Porter has declared no uncertain opinion upon this subject, and we have him expressing his satisfaction at the general reception of that opinion thus:—"In this country I have not for some years heard of tracheotomy having been seriously proposed for the relief of any form of croup, and I feel considerable satisfaction in the reflection that I have in some small degree contributed to the establishment of so desirable a practice." These words were written thirty-nine years ago, when the operation was rarely practised. But I cannot doubt that had he lived until now, and thus been conscious of the wider knowledge that has come to us concerning this proceeding, and the more favourable results, he would, like Professor Spence, be found among the advocates of it.

I do not intend to speak of any other aspect of the question than the operative. It will for my purpose be more profitable to consider some of the points which have been urged against tracheotomy, and which have served to strengthen, if they have not created, the opposition to it.

One of the first is, that it is a very fatal operation. That is unfortunately true, but it is not a fair ground of objection. If we adopt it we at once put an end to all surgical work, for there is no part of it in which the surgeon can guarantee security against death. There is a high average of fatality in a great number of operations that are unhesitatingly undertaken by surgeons every day. So ordinary a proceeding as amputation gives an average death-rate of 38·72 per cent. after injury, and of 26·12 after disease. Descending to particulars, amputation of the thigh gives a mortality of 57·41 after injury, and of 27·23 for disease, or an average of 41·60. Tracheotomy in croup has been followed by a death-rate which ranges from 60 to 90 per cent., while in groups of cases it has given a much less percentage. In judging of relative mortality, however, it must not be forgotten that all the conditions are in a majority of cases unfavourable to success. The child has usually been ill for some days, and is brought into hospital in the last stage, not having been under medical care at all. Or it may be that he has been in the charge of one who, having reliance upon medicinal treatment, has waited in vain to see the symptoms improve under the influence of mercury or tartar emetic. The patient is almost comatose. His lips are blue, his face pale, his lungs have become engorged owing to prolonged obstruction, the blood is loaded with carbon, and every beat of the heart is sending to the nerve centres so much poison. Is it at all strange that under such circumstances there should be a high death-rate? The patient has already had his vitality almost hopelessly impaired. The lungs and the nervous system have no time to recover their tone, and the little sufferer, after the first faint flicker, gradually sinks and dies. If in the ordinary run of surgical cases conditions were of a similarly unfavourable nature, we should hardly be surprised at a high mortality.

But as bearing upon the question of death-rate, it will be interesting to look into some statistics of the results of this operation in different parts of the world in croup and diphtheria. The earliest were collected in 1839, and were reported to the Parisian Academy of Medicine. In those days tracheotomy was in general disfavour, and 140 cases only gave 28 recoveries, or 20 per cent. Of these Trousseau contributed 80, with 20 recoveries, or 25 per cent. In 1858 three separate lists showed 175 cases, with only 10 successes, or 5·7; 150, with 57 successes, or 38 per cent.; and 185, with 74 successes, or 40 per cent.

In the Hôpital des Enfants Malades, up to 1849, the operation had been performed 49 times with one recovery. After that date there were—

	Operations.	Recoveries.
From 1850 to 1862 . .	991	233
Hôpital Sainte Eugénie—		
From 1854 to 1869 . .	1,261	299
	2,252	532

or 23·6 per cent.

American records show a total of 325 operations, with 84 recoveries, or 25·8 per cent.

I am not able to place before the Society statistics of the operation in this city or country. It has been very seldom performed here in cases of croup or diphtheria. But I may record these figures regarding English and Scotch practice:—

	Operations.	Recoveries.
Spence . . .	103	34
Buchanan . . .	46	17
Cruikshank . .	11	8
Whittle . . .	11	10
Fuller . . .	7	3
H. Smith . . .	3	0
Ransom . . .	3	0
C. Evans . . .	5	1
Howse . . .	3	3
	192	76

equal to 39·5 per cent.

The figures which I have given include operations performed on patients at all ages; but Bourdillat shows that there is a direct relation between age and result. Thus, (*a*) while few "under two years are saved, very few over eight or nine, and adults seldom or never," the largest number of recoveries appears to be from 5½ years to a little over six.

Under	2 years,	3 out of 100
At	2 „	12 „
From 2½ to	3 „	17 „
„ 3½ —	4 „	30 „
„ 4½ —	5 „	35 „
„ 5½ —	6 „	38 „
Above	6 „	41 „

The percentages noted above show nearly 40 per cent. of recoveries—a result which may fairly be asserted to be brilliant in view of past failures. Remembering that in the greater number of cases the patient was *in extremis* when the trachea was opened, and that by more or less prolonged obstruction to respiration he had conditions present which invited a fatal termination, I think there cannot be a doubt that a large number were saved from death by the operation. That is a fact which a surgeon can scarcely fail to realise.

But, after all, in viewing a question of this kind we ought not to be bound up rigorously by statistics; and still less should we be deterred from interfering because death will probably occur, and we may have to bear some odium. As a matter of fact, there are many procedures in surgery in which we ignore statistics. We operate with one of two objects—to cure or to palliate. We amputate at the hip-joint because we give the patient a chance of life, although a very distant one, or relieve him temporarily from suffering. We amputate breasts for malignant disease, although we know that the affection almost invariably returns, and that the patient's life is not much prolonged. And yet surgeons who do these things will refuse to make an opening in a child's trachea in a case of croup or diph-

(*a*) Cohen on Croup. Pp. 21 and 23.

theria, the prominent symptom being the local obstruction. Surely, if death do follow it is a less terrible one than that which shocks the feelings in a case dying of slow suffocation. I confess I am quite unable to appreciate the grounds upon which the resistance is made. It seems to me that it would be as reasonable to decline to interfere in a case of strangulated hernia because the surgeon thought the gut was gangrenous, and that the patient would probably die.

One who has had more experience of tracheotomy than any now living, having operated in over 200 cases, thus declares his opinion: (*a*)—"For my part I am quite determined not to allow myself to be discouraged, but to preach tracheotomy with the greater conviction in proportion as its success increases, and did the proportion remain what it was ten years since I should still proclaim the necessity of the operation, nor cease to say that it becomes *a duty*—a duty as imperative as the ligature of the carotid artery after a wound of that vessel, though death follows the operation as often certainly as recovery;" and from very many strong advocacies of the proceeding, I may further quote these words of Rilliet and Barthez (*b*)—viz.: "The utility of tracheotomy in the treatment of croup cannot at this day be denied; numerous cases of children snatched from a certain and imminent death reply victoriously to any doubts that may be raised as to the truth of this assertion."

In England and Scotland, such successes as those of Spence, Buchanan, Whittle, Marsh, and others, speak irresistibly on the same side.

There are other objections which have been urged against the operation, such as the accidents which may occur while it is being performed and the complications which may subsequently arise. But surely there is no surgical proceeding which may not be so opposed. Arguments of this sort prove too much, and are hardly deserving of a serious reply. It is alleged also that the admission of air to the lungs, without having passed through the nares or mouth and so obtained warmth, is apt to produce bronchitis and pneumonia. That difficulty, however, is now got over by means of a moistened atmosphere of elevated temperature, such as I have referred to in the notes of two of the cases.

There are some points in connection with the indications for operation and the site of the opening to which I may briefly refer. Professor Porter thinks there can be no object in operating when the membrane is red and swollen in the first stage. The incision will more likely aggravate the disease. "When the adventitious membrane has been formed, there is some reason to think that in the great majority of cases sufficient mischief has been already accomplished to render the recovery very problematical" (p 38). But there can be no doubt that even in the non-exudative stage operation may be necessary, for there may be apnœa from simple spasm of the glottis, or from the temporary paralysis of the expanding muscles of the larynx (Niemeyer). There is no sign by which we are able in every case to determine the presence or absence of deposit, and we must therefore be led by the general symptoms. Heuter points out that there is one symptom of special importance which indicates tracheotomy—namely, the sinking inwards of the anterior wall of the thorax, especially of the lower end of the sternum. When to this is added the well-known abnormal action of the nostrils which always occurs in marked difficulty of respiration, and the blue colour appears in the lips, he at once proposes the operation. Spence and others hold very much the same view. The great danger, I think, lies in waiting too long and thus allowing the patient's strength to run down. The exhaustion brought about by the struggles to breathe is increased by the impure blood and the consequent impairment of the functions of the principal organs. I do not at all advocate recourse to the knife in the earliest stages, but when the indications of serious and increasing obstruction are evident, I think the surgeon ought speedily to interfere. The disease is so rapid in its progress and its effects that there is no time for the ordinary remedies to act satisfactorily. To continue depressants then will only further lessen the chances of the patient's recovery. Calomel will not remove the membrane any more than it will cure a strangulated hernia. The one prominent symptom is apnœa, and in the present state of our knowledge we must rest satisfied with treating that. In such a case I think our course is clear. What is needed is air, not medicine; an opening in the trachea, not mercury.

A case in which operation was proposed and refused was brought under my notice by my friend, Dr. Francis B. Kane, now of San Francisco. It occurred in his practice as Surgeon of Jervis Street Hospital in this city. I had an opportunity of examining the parts after death, and I freely joined in the regrets that were expressed that the trachea was not opened. The disease was confined to the larynx, which was almost shut off from the trachea by a horizontal septum. The trachea and bronchi were without any deposit. In this case there seems every reason for saying that life would have been saved had the operation been performed, and air been admitted to the lungs, and that no amount of medicine would have rescued the child from death.

A question upon which a good deal has been written is the portion of the trachea which should be opened. Very many practice the incision below the thyroid isthmus, chiefly because we are more likely to get beyond the situation of the membrane should it be confined to the trachea. But it may be objected to this operation, that it is one of much difficulty and of no little danger. In an infant the knife comes into alarming closeness to very large vessels, and I have seen severe hæmorrhage occurring from the wounding of an engorged thyroid vein. Holmes, in his recently-published work, mentions that he lost a case by wounding a branch close to the innominate vein. There is increased difficulty in introducing the tube, and in the subsequent progress of the case a danger of wounding the innominate vein by the edges of the canula. Howse ("Guy's Hosp. Reports," 1875, p. 503) states that he has seen two fatal results from this cause, not to mention ulceration of the trachea by the tube tilting against it. In both cases in which I operated I adopted the higher incision. In the first there was a little bleeding from a wound in the isthmus; in the second not a teaspoonful of blood was lost. The trachea was exposed with comparative readiness, and in neither was there any difficulty in introducing the tube. Heuter advises that the cricoid should be divided, but those who practise the high operation generally stop short of it.

I am not, of course, to be understood as advocating tracheotomy as an exclusive line of treatment. I believe that medical treatment often does good, but that it more often fails, and my only wish is to have this operation recognised as a more reliable aid than it has hitherto been. Formulating my views I may put them thus:—

I. Croup may be treated medically in the early stages.

II. If the disease advances and obstruction increases in spite of medicine, tracheotomy ought to be undertaken, the symptoms already mentioned being looked for.

III. The danger of aggravating the disease by opening the trachea has been exaggerated, and is, with ordinary precautions, *nil*.

IV. Even as a palliative measure the operation is justifiable, and, considering the chances of recovery, ought to be recommended.

V. The opening is more easily made above the thyroid isthmus, and is as effectual as when made below it.

I have extended my observations to a greater length than I purposed, but the importance of the subject must be my excuse. I am anxious that in Ireland we should not look with so much distrust upon tracheotomy, or present an unbending opposition to its more general adoption. For myself, I am quite satisfied that it is a proceeding not only justifiable, but demanded at the hands of the practi-

(*a*) Trousseau, Archv. Gen. de Med., Mars, 1855, p. 259.
(*b*) Mal. des Enfants. 2ème ed. t. i., p. 337. Meigs and Pepper, 105.

tioner in a large number of cases that come under his notice. The prejudices and misfortunes that surrounded the operation of ovariotomy were no less strong and discouraging, but they have both been overcome by the perseverance of its advocates. With experience have come increased skill and knowledge, until that operation stands admittedly the greatest triumph of modern surgery. I believe that the reasonableness of operative interference in croup will commend itself to Irish surgeons, and that it will in time present a more favourable result than that which I am able to lay before you. In conclusion, I may quote the words of the distinguished Professor of Surgery at Edinburgh, Mr. Spence: (a)

"I think it right, however, to warn my younger brethren that it will require some effort to bear up against discouraging results. I know of no class of cases in which the experience is so painful—an average gives no idea of it. You may have five or six cases in succession all proving fatal before you meet with one redeeming success, but then you have the temporary relief almost invariably afforded to the little sufferer—the resuscitations in some cases apparently dead, and if you persevere the average of success will come. Above all, we must recollect that, however disagreeable or unpleasant the operation may be to ourselves, we are bound to lose sight of that to give the patient the only chance for life."

THERAPEUTICS: INCLUDING THE PHYSIOLOGICAL ACTION OF MEDICINES.

By W. Handsel Griffiths, Ph.D., L.R.C.P.E.,

Licentiate of the Royal College of Surgeons of Edinburgh; Lecturer on Chemistry in the Ledwich School of Medicine, Dublin; Editor for the *Edinburgh Medical Journal* of the "Monthly Reports on the Progress of Therapeutics"; Corresponding Member of the Therapeutical Society of Paris; Hon. Member of the Ontario and Chicago Colleges of Pharmacy, &c.; Librarian to the Royal College of Surgeons in Ireland.

(*Continued from page* 46.)

With reference to the action of arsenic on the skin, it may be stated that in minute doses it acts as an alterative and tonic, and is of extreme value in the treatment of cutaneous affections, *more especially when of the scaly or of a relapsing character*. In the treatment of chronic eczema, lepra, psoriasis, relapsing pemphigus, and lichen ruber, probably no remedy is equal to, certainly none superior to, arsenic. In a recent article in the *Medical Times and Gazette* Mr. Jonathan Hutchinson has brought forward a mass of incontestible evidence as to the value of arsenic in pemphigus, an opinion which is not shared by Hebra. Mr. Hutchinson states his belief that arsenic is a specific for the state of health on which relapsing pemphigus depends. In other forms of skin affections, as chronic impetigo, pityriasis, and urticaria, arsenic may be beneficially employed *when the inflammatory symptoms have subsided*. In scaly skin diseases, when of a syphilitic origin, Donovan's solution will be found of value. It is affirmed by some dermatologists that the combination of iodide of potassium with arsenic enhances the efficacy of the latter agent in the treatment of skin disease. Cleland attributes much of the efficacy of arsenic in the treatment of skin affections to the increased nutrition of the epithelial surfaces to which it gives rise. (b)

Arsenic has been employed beneficially in the treatment of several affections of the nervous system. In chorea it has been extensively employed, and Radcliffe speaks favourably of the hypodermic administration of Fowler's solution in doses of from 3 to 12 minims in this affection. In the *British Medical Journal*, May 1, 1875, Dr. Eustace Smith insists on the necessity of giving the drug in full doses in chorea, and he calls attention to the tolerance of children for arsenic. To a child between five or six and twelve years he would give 10 minims of Fowler's solution thrice daily after meals.

Many instances of the efficacy of arsenic in the treatment of neuralgia, particularly when intermittent, are on record. Some physicians hold that to be of use in this affection the dose of arsenic must be gradually increased until decided toxic effects show themselves, when the administration of the drug should be temporarily suspended. In chronic rheumatism, characterised by nodosity, or when of a syphilitic origin, and especially when following the imprudent use of mercury, arsenic has proved of the greatest service.

It is in the treatment of intermittent fever that arsenic has been found most useful. In the chronic forms of intermittent fever arsenic is probably equal to quinine, but in recent attacks it is inferior to that drug. In cases in which quinine fails arsenic frequently effects a cure, and it cannot be too strongly impressed on the mind that a combination of these drugs will frequently cure when the administration of either separately has signally failed. I have recently had two striking examples of the truth of this statement under my own immediate observation. In the *Madras Quarterly Journal of Medical Science* for August, 1865, Dr. H. C. Brodrick records 177 cases of intermittent fever successfully treated with arsenic. The dose usually administered was half a drachm of Fowler's solution thrice daily after meals. Some observers affirm that combination with ammonia increases the efficacy of arsenic in the treatment of intermittent fever. Sistach corroborates the opinions held by Frémy, Fuster, and Girbal, that the febrifuge action of arsenic manifests itself more promptly in the tertian than in the quotidian variety of intermittent fever. He regards arsenic as being as effectual, but not so rapid in its action, as quinine. The slowness of its action and its tendency to aggravate the gastro-intestinal symptoms render arsenic unsuited for the treatment of remittent fever and the pernicious variety of paludal fever. (a)

In intermittent gastrodynia and in periodical headache arsenic frequently effects a cure. Lastly, in atonic menorrhagia, in dysmenorrhœa, in leucorrhœa, amenorrhœa, and in uterine disorders associated with rheumatism, arsenic has proved of service.

When the medicinal dose of arsenic is exceeded it gives rise to loss of appetite, nausea, vomiting, epigastric pain, and purging; not unfrequently an eruption of urticaria, pityriasis, or psoriasis occurs. When the use of arsenic is continued for some time it sometimes occasions a characteristic puffiness of the face, with œdema of the eyelids, followed by dropsy of the abdomen and limbs.

The following account of the symptoms of chronic arsenical poisoning is from the pen of Stille: (b) "Loss of appetite, nausea, derangement of the digestion, diarrhœa or constipation, with thirst, salivation, tenesmus, colic, and intestinal cramps; the respiration is laboured and painful, a sense of oppression is experienced, with pain in the breast, cough, extreme wasting of the flesh, and hectic fever; the limbs grow tremulous, and not uncommonly they become paralysed, especially the lower extremities; pains in the whole body are experienced, but are very constant in the hands and feet, and are a source of extreme suffering; stiffness and contraction of the extensor muscles of these parts succeed, numbness gradually invades the extremities, and the mental faculties subside into insensibility and torpor; œdema of the face and extremities, and even general anasarca are not unusual; and at the same time the hair falls out, the epidermis scales off, pustules and other eruptions ending in ulceration attack the skin, which assumes a lifeless, earthy hue; the countenance if not œdematous, is sunken, the conjunctiva is strongly injected, and a reddish circle surrounds the eyes."

In general, the symptoms of acute arsenical poisoning are referable to gastro-intestinal inflammation; they are—

(a) *Archiv. Gén. de Méd.*, Sept., 1875.
(b) "Therapeutics and Materia Medica." By Alfred Stille, M.D. Third Edition. Philadelphia. 1868.

violent abdominal pain, nausea, and vomiting, with œsophageal spasm, cramps of the bowels with bloody and offensive stools, insatiable thirst, notwithstanding that profuse salivation is a frequent occurrence, irritation of the urinary and genital organs, and sometimes suppression of urine or hæmaturia, the respiration becomes hurried and laboured, the pulse low, feeble, and irregular; sensibility and consciousness are generally retained until the last moments of life. Occasionally symptoms indicative of an impression on the nervous centres, as coma, or of extensive depression of the circulation, predominate.

Symptoms of poisoning will ensue whether the arsenic be taken internally or whether it be introduced into the system by application to denuded skin, to a mucous membrane, or to a wound. Numerous cases of poisoning from arsenical vapour are recorded.

Post-mortem examination reveals evidences of inflammation of the gastro-intestinal mucous tract, and fatty degeneration of the liver, kidneys, and voluntary muscles. Curious to say, the signs of gastro-intestinal inflammation are more conspicuous when the arsenic is introduced into the system through a wound than when it is taken into the stomach.

In cases of arsenical poisoning the stomach-pump should be at once employed, emetics and demulcent drinks administered, and large quantities of the reputed antidotes should then be given. These latter are moist peroxide of iron, which was first recommended by Bunsen and Bertholet, and light magnesia, which was suggested by Bussy. Both of these antidotes act by converting the arsenic into an insoluble salt. Animal charcoal and lime-water have also been proposed as antidotes.

The following rules relative to the administration of arsenic should be carefully observed :—

1. It should never be given where there is a feverish state of the system; a quick pulse and a hot skin contraindicate its employment.
2. It should be given shortly after meals—never on an empty stomach.
3. It should not be given in the solid form, nor should it be given in increasing doses. As a rule, five minims of Fowler's solution should be the maximum dose for an adult.
4. The dose should be diminished, or the administration altogether ceased, on the occurrence of pain in the epigastrium, nausea, or irritation of the eyelids.

I have notes of several cases of remarkable susceptibility to the action of arsenic.

ACIDUM BENZOICUM, AMMONIÆ BENZOAS, AND BENZOINUM.

Tincture of benzoin has been recommended as an application for sore nipples, and for the same purpose a saturated alcoholic solution of benzoin mixed with an equal proportion of glycerine is often used. A mixture of one part of the compound tincture with four parts of glycerine constitutes an excellent application for chapped hands and lips. A solution of two drachms of the simple tincture in a pint of rose-water is much used as a cosmetic, and is known as "virgin's milk."

Benzoin exerts little or no influence on the digestive functions, but is apt to cause disorder of the stomach, owing to its irritant properties. The compound tincture has been used in chronic dysentery; and when the stomach is intolerant of it, it may be administered as an enema made up with mucilage.

Gum benzoin, benzoic acid, and benzoate of ammonia exert a specific stimulant effect on the pulmonary mucous membrane, and the former was formerly much used in chronic affections of the bronchi; it was also formerly used in the treatment of asthma. Benzoin is contraindicated as an expectorant in all acute cases. The compound tincture is sometimes used for fumigation in chronic throat and laryngeal affections with loss of voice. Morell Mackenzie uses an inhalation of one drachm of the tincture in twenty ounces of water at 150° F.

Falck recommended benzoic acid as a remedy in jaundice, but it is only applicable to such cases as arise from obstruction of the biliary secretion; benzoate of ammonia is of great use in restoring the colour of the skin in jaundice.

Benzoic acid acts as a diuretic. Dr. Ure and others believed that it causes uric acid to disappear from the urine and to be replaced by hippuric acid; but Keller and Garrod have shown that the uric acid remains unchanged, and that the benzoic acid is converted into hippuric at the expense of the urea. Except in those cases of jaundice where there is a deficiency of glycocin (sugar of gelatine), benzoic acid, by combining with the elements of the latter, becomes converted into hippuric acid, and as such is eliminated from the system, thus :—

$$\underbrace{HC_7H_5O_2}_{\text{Benzoic Acid.}} + \underbrace{C_2H_5NO_2}_{\text{Glycocin.}} = \underbrace{HC_9H_8NO_3}_{\text{Hippuric Acid.}} + H_2O.$$

In 1831 Wœhlér first suggested that during digestion benzoic acid is converted into hippuric.

Benzoic acid has undoubtedly proved useful as a solvent of uric acid and of urates, and I have treated two cases marked by a tendency to the formation of uric acid calculi very advantageously by a combination of benzoic acid with phosphate of soda, using cinnamon-water as the vehicle. Cinnamic acid, which is contained in cinnamon bark and in balsams of Tolu and Peru, is, like benzoic acid, converted into hippuric acid in the system.

In vesical irritation in cases of phosphatic urine, *when depending on disease of the bladder*, benzoic acid is a valuable agent in keeping the urine acid. In incontinence of urine without altered constitution of this secretion benzoic acid has been found of value, but chiefly so in the nocturnal incontinence of children. Benzoic acid has often been found useful to correct the fœtor of urine in cases of irritable bladder from enlarged prostate. In all these cases the ammonia salt is preferable to the acid, on account of its greater degree of solubility.

Salkowski finds benzoic acid to be superior to salicylic acid as an antiseptic, a result opposed to that obtained by Kolbe. (*a*)

A lotion of benzoic acid, or benzoate of ammonia, relieves the itching of urticaria and other skin affections.

Benzoic acid is said to act as a stimulant to the sexual organs. Benzoin has been given advantageously in chlorosis and some uterine disorders.

Clinical Records.

INTERMITTENT APHASIA IN THE INSANE.

By John G. Thornley, M.D.,
Assistant Medical Officer Leicester County Asylum.

The following case of what may be termed intermittent aphasia is, as far as I know, unique of its kind :—A. B., a female patient, æt. 32 years, has suffered at intervals for the past two years from the following symptoms: She was admitted into this asylum in 1873, and about two years ago it was first observed that she was suddenly deprived of the power of expressing thought, except the following sentence. If asked any question on any subject, such as, how do you feel? or how do you like your medicine? she would immediately reply, "There is no blood at my heart." If the question was pressed by repeating it a second or third time, she would either nod or shake her head, accordingly as she wished you to have an affirmative or negative answer. She can communicate her thoughts, feelings, and wishes by writing, but cannot pronounce any words other than those which form the sentence, "There is no blood at my heart."

The aphasic state remains on her for irregular periods, sometimes two or three months, when suddenly the power of speech returns, and remains for two or three days, dur-

(*a*) *Berliner Klin. Wochenschrift*, No. 22, 1875.

ing which time she can of course describe her feelings and thoughts with perfect fluency, when again the aphasia suddenly supervenes, and without warning of any kind. Sometimes the aphasia passes off during the night, at other times during the day. Aphasia is often associated with right hemiplegia, but in this case there is neither hemiplegia nor paraplegia, nor paralysis of any kind; it is associated in this case with persistent and intense anæmia and menorrhagia. Although the appetite remains fair, she has had prolonged courses of citrate of iron and quinine, with various tonics and stimulants, but without any good result. This patient makes known her desires by various nods and gestures—in fact, she has a fair command of pantomimic language.

The peculiarities in this case are, that with the exception of the patient being able to pronounce one short sentence, the aphasia is complete; it is also intermittent; it is not associated with paralysis of any kind, but is concomitant with intense anæmia, and extensive patches of ecchymosis on the legs and arms. There seems also to be a deficient power of the will, as on any stranger presenting himself in the ward she immediately addresses him in the stereotyped sentence, and seems impelled to do so. While the aphasic state lasts the appetite and general health of this patient become indifferent; when the aphasia passes off, a decided improvement takes place in her general health.

It is almost unnecessary for me to enter into the question as to the localisation of the centre for the power of speech—the principal theories, however, being those of Van der Kolk, who held that the centre of speech was in the corpora olivaria; of M. Bouilland, who considered it to be in the anterior lobes of the brain; of M. Dax, who placed it in the left cerebral hemisphere; and lastly, that of M. Broca, who places it in the posterior part of the third left frontal convolution.

Each and all of these theories have been, I think, satisfactorily disproved, several cases having been observed by M. Vulpian where both corpora olivaria have been diseased, and yet speech remained perfect to the last. Bouilland's theory has been upset by a case recorded by Cruveilhier, where a congenital idiot could pronounce words distinctly articulated, yet after death there was found to be congenital absence of both anterior lobes. Dax's theory is not improved by the instance related by Legrand, where a man was shot in the head during the French Revolution of 1848, and although the left frontal lobe had been completely shattered by the discharge of the gun, the power of speech was not affected in the slightest; and I think Broca's theory will not stand against the cases recorded by MM. Vulpian, Trousseau, and Charcot, where cases of aphasia existed whilst the third left frontal convolution was found quite perfect and healthy.

The localisation of the speech centre which has lately attracted the attention of medical men all over the world is evidently the outcome of the phrenological doctrine which was first definitely given expression to by Gall, although the ancients possessed crude notions of the functions of the brain and believed in centre localisations, as evidenced by Aristotle, who placed the sensorium commune in the heart; Servetus, who lived in the sixteenth century, believed that the fourth ventricle was the seat of the memory; and René Descartes believed that the pineal gland was the seat of the soul.

I am of opinion, however, that any unbiased reader who has carefully studied the objections brought against the localisation of the speech centre will agree with Dr. Maudesley that there is no more a centre for speech than for writing, dancing, or gesticulating; but still I am of opinion that the craniological doctrine of Gall, although arbitrary, and in many respects imperfect, is worthy of the attention of every scientific observer. The cause of aphasia is one of the most mysterious subjects in psychological medicine. Dr. Richardson showed that by freezing the cerebrum of animals he could completely suspend various of its functions, without leaving any trace of permanent mischief. And I am of opinion that in the above case of intermittent aphasia the cerebral change must be owing to some electrical, thermal, chemical, or circulatory alteration in the brain, and not to any organic change of structure.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE fourth meeting of the session was held on Friday, January 21st, the President, Mr. EDWARD HAMILTON, in the chair.

Mr. B. WILLS RICHARDSON (Hon. Sec.) having read the minutes of the previous meeting, they were confirmed.

MELANOTIC CANCER OF EYEBALL.

Mr. CROLY said he thought the recent specimen which he exhibited was worth bringing under the notice of the Society. It was a very well-marked specimen of what was known as melanotic cancer of the eyeball. He would briefly detail the history of the case, with the microscopic appearances. The patient from whom the specimen was taken was a labourer named Michael Brophy, aged 39 years, and was admitted into the City of Dublin Hospital on the 21st of December, 1875, with a protrusion of the left eyeball. He stated that about four years ago he got a severe wetting, and that inflammation attacked his left eyeball, and that he became blind almost immediately. No treatment seemed to be of any avail; the eye remained in that condition, but of its natural size, until March last, when it commenced to protrude from the socket, and at last attained a very large size. It was difficult to discover the cornea, and there was a general bulging of the choroid coat, together with a black appearance of the entire eyeball. There was not very much pain. He (Mr. Croly) extirpated the eyeball on Tuesday morning last, and found, on the removal of it, that the tumour presented the very black appearance now observable, and on the introduction of one of his fingers into the socket for the purpose of clearing it out his finger was stained with the black pigment usual in this disease. The Curator of the Museum, Mr. Barker, had very kindly examined the tumour, and had written to Mr. Croly the following letter concerning it:—

"Royal College of Surgeons in Ireland,
"Museum Department,
"Dublin, 21st January, 1876.

"MY DEAR CROLY,—The specimen you gave me yesterday presents all the ordinary appearances of melanotic cancer. It is full of cancer cells, which appear surrounded by pigment particles. There are also numerous nucleated cells, oval or rounded, perfectly free from pigment. As far as I can see, the pigment does not necessarily constitute an element of the cancer, but that cancer having attacked the neighbourhood of the choroid, the cells and the contents of the choroid were developed to an extraordinary extent. There were also in this specimen a large quantity of highly refractive very minute particles. The power I used was about 510 diameters.

"Yours faithfully,
"JOHN BARKER."

On looking into Wilks' book on this subject, he (Mr. Croly) found that he stated that melanotic carcinoma was only distinguished from the medullary by the more or less considerable amount of pigment contained in the cells of the trabeculæ forming the areolæ. It might be so great as to give a dark inky colour to the tumour. In the melanotic cancer there were also large areolæ enclosing nests of pigmented cancer cells. That was what Wilks said on the subject. The melanotic cancer was extremely dangerous, and was very prone to recur at an early age. Von Graafe stated that he did not remember any case in which the apparent cure exceeded four years. In the majority of cases the disease recurred locally or in other organs within three, six, or twelve months. The only other fact in connection with the case was of some interest, and he (Mr. Croly) thought it showed that the disease was of a very formidable nature. It was that after removing the tumour, and when he introduced his finger to explore the floor of the orbit, near the entrance, for the optic nerve, he found that the bone was completely eroded. There was, however, nothing to be done in this case but the removal of the tumour.

Mr. THOMSON then read a paper on

TRACHEOTOMY IN CROUP,

which will be found on page 107.

Mr. RAWDON MACNAMARA said that Mr. Thomson's paper was one of the most interesting communications that had been brought before the Society for some time, and it was full of practical importance to Irish surgeons, because it was not flattering to them, it was not complimentary to them, but it was trying to show them some of their shortcomings, and, in a kindly spirit, to bring them to another view than that which they had hitherto held with reference to this operation. The question of tracheotomy was a most interesting and important one, and it had been defended in one way by the reader of the paper that made him (Mr. Rawdon Macnamara) inclined to ask a question, and it was a question that had something of a personal character, because it had been asked him in one of the medical journals. He had stated the results of capital operations in this city, and he was taken to task in the Journal of the British Medical Association with regard to the ground on which he had made the assertion as to the result of capital operations in this city. His friend Mr. Thomson had in his paper quoted the result of capital operations being so unfortunate as being a justification for operations in croup—that they did not hesitate even because capital operations were so unfortunate, to operate, and that therefore, though they might not have a sufficient number of successes in tracheotomy—applying the same reasoning that they were justified in operating for croup. He (Mr. Rawdon Macnamara) stated on the occasion on which he was taken to task that the percentage of mortality—and these statistics were perfectly different from those which Mr. Thomson had quoted—from operations—amputations in any part; and he repeated the statement now: that the statistics quoted by Mr. Thomson were not at all applicable to Irish surgery. He would like to know where Mr. Thomson got his statistics. He (Mr. Macnamara) thought the statistics quoted that evening as to the mortality in important operations were not at all applicable to operations for tracheotomy. Another point which he wished to allude to was that Mr. Thomson quoted the words of Mr. Spence as the concluding passage of the paper. He (Mr. Macnamara) could not help saying that passage forcibly reminded him of a passage of Brettonneau where he stated that some of the proudest and happiest moments of his life were those in which he had snatched from death a child and restored it to its parents, and it appeared to him (Mr. Macnamara) to be almost a translation of his words. The fact was, no doubt, that operations of tracheotomy had been performed in which they could boast of the same success in regard to them as in amputations of limbs, but they could not justify them in the same way; and he must say that the paper that had been brought forward—in the most laudable spirit no doubt—contained results that were anything but encouraging, for it appeared that there were three cases reported, two of which were operated upon, and both the children died. In the third case, in which there was no operation, the patient also died. That certainly was not encouraging to Irish surgeons, especially when they had records in other countries of brilliant success, and they were not encouraging compared with their Irish experience. He thought a great deal with regard to this was to be attributed to the fact that the operation was invariably performed *in extremis*—that it was the last resource, in which nothing was left but for the surgeon to operate or the patient to die. He knew there were a great many cases where, from tartar emetic or mercurial treatment, or otherwise, they had success, and that if in those cases they had operated, it would be said that the result would have been that they ought not to have operated—that they recovered in spite of operation. One of the great difficulties attending statistics was that they showed only that when it was found utterly useless to do anything else *in extremis* the knife was had recourse to. He thought such statistics brought with them a certain amount of reproach on the surgeon. It had occasionally been his lot to have recourse to the operation when he saw that the case was one of a moribund character, and he confessed that by his operation he felt that he was only bringing operative surgery into disrepute. The great question was whether early operations were attended with greater success, and there came the intense difficulty whether curative treatment short of operative treatment would succeed. He thought there was great difficulty attending that point. He therefore believed that it was only by bringing such questions before the Society, and by the members discussing them in a candid and impartial spirit—it was only in that way that important questions could be solved.

Mr. STOKES said he was only one of many who would endorse what Professor Macnamara had said with regard to the great surgical importance of the communication which the Society had just heard from Mr. Thomson. There could be no doubt as to the truth of what he had said in reference to the feeling against the operation of tracheotomy in croup, which had directly resulted from the teachings of the eminent professor he had mentioned, and also another eminent professor he (Mr. Stokes) would mention, Mr. Abraham Colles. There could be no doubt, from the teachings of those gentlemen years ago, of the great reluctance that practical operating surgeons had in this city and in Ireland generally to the performance of tracheotomy in croup. The main argument that had been urged by Professor Abraham Colles, Mr. Porter, and others who had written on the subject, had been the difficulty, the impossibility of differentiating the cases as to where the false membrane was exuded above and where it was exuded below the point where the tracheotomy tube was inserted, and it was in consequence of the difficulty that surrounded that point that it was sufficient to make surgeons decline operating in these cases. He thought that was a wholly wrong and an unphilosophical view to take of the subject. He himself had had some experience—he had operated himself in croup, he had treated cases medically, he had seen these cases operated on by others, and he had seen them treated by other surgeons, and his experience had been this—that in the fatal cases in which the operation had not been performed the patients had all died of asphyxia, and in none of the fatal cases where the operation had been performed had the cause of death been asphyxia. He thought that was a great and strong argument in favour of the operation. He had seen a case where the operation was performed and in which clearly the exudation extended far beyond the point where the tracheotomy tube was inserted, and he had seen students sitting up with patients for two days and nights and with feathers and sponges keeping the trachea clear of the false membrane, and at times taking vast shreds an inch and a-half in length out of it, and he had seen that patient recover. He thought, if there was no other case, that was sufficient to make them come to the conclusion that the operation was justifiable under those circumstances. He thought, in dealing with the question, that Mr. Macnamara had drawn attention to the difficulty of establishing when the operation should be performed after medical treatment ceased to be of avail. He (Mr. Stokes) thought that an eminent German surgeon—Roser by name, professor of surgery at Marbourg—had pointed out very clearly and well the rules which should guide them on that point. He stated that in dealing with this question two stages should be considered—one, the stage of asphyxia, and the other, the stage that immediately preceded asphyxia, or the stage that threatened asphyxia. In the latter stage they had the patient struggling violently to overcome the mechanical obstruction. They had the patient's face red, the pulse throbbing, and a restless getting up in the bed and seizing at everything, in the hope of obtaining relief. When that stage passed away the patient's lips became blue, the face livid, the patient became covered with cold sweat, the pulse failed, and asphyxia set in. It was before that came on that Roser held that the operation of tracheotomy should be performed, and if the surgeon arrived too late, when the stage of asphyxia came on, that even then the operation should be performed, though the prognosis in that stage should be very bad. Unfortunately, in his (Mr. Stokes') case, and also unfortunately in the three cases that Mr. Thomson had drawn attention to, the point at which the operation should be performed had been allowed to go by, not through Mr. Thomson's or his (Mr. Stokes') fault, but through the fault of the friends or relatives of the patients. He (Mr. Stokes) thought they should, in considering this subject, try if possible to determine the exact point at which the operation should be performed, always remembering that medical treatment should, in the first instance, be had recourse to if the case be got in time for it; but if the symptoms did not yield, then they should not hesitate to perform the operation of tracheotomy. The statistics which Mr. Thomson had quoted were very important, but the statistics of other surgeons were equally as important. The statistics of Langenbeck and Roser would show that so large a proportion as 40 per cent. of cases in croup had terminated successfully. That should be con-

sidered of great importance when debating the propriety or otherwise of the performance of tracheotomy in this disease.

Mr. B. F. M'Dowell thought there were two important points which had tended to bring the operation of tracheotomy in croup into disrepute, in this country particularly. These were the teachings of Mr. Abraham Colles, and also the strenuous condemnation of the operation by the late Mr. Porter, together with the absence of anæsthetics. He (Mr. Porter) most strongly condemned it, as far as he (Mr. B. M'Dowell) recollected, in this disease. Another point was that the operation was most commonly performed below the thyroid isthmus. In two papers he read before this Society in the years 1870 and 1872 he recommended that the operation should be performed above the thyroid isthmus, whether for croup or laryngitis. That simplified the proceeding very much, and lessened the risks from after consequences. He felt that in a great number of cases the lives of the children might be saved if the operation was performed at the proper time; but, unfortunately, the parents would not hear of the operation being performed until the patient was in a state of physical exhaustion. There was another point to which he was glad to perceive that Mr. Thomson had alluded—that was with regard to the condition of the atmosphere during and after the operation. That was a point which lessened the risks of the operation very materially. The late Mr. Porter, in his monograph on the subject, stated that he never knew a case die after tracheotomy that did not die of bronchitis. He (Mr. M'Dowell) had performed the operation three times successfully for laryngitis, and not one of those cases suffered from bronchitis, and he attributed that to the state of the atmosphere. He thought that if the temperature was kept up to 70° or 75°, and the air well charged with moisture before, if possible, but certainly after, the operation, the risks of bronchitis and pneumonia were simply *nil*. There was no approach even to bronchitis or pneumonia in his cases. He agreed with Mr. Thomson in his observations with regard to the time at which the operation should be performed. There was a period—particularly, he thought, in croup—it was not of so much consequence in laryngitis—before the patient was exhausted, that the operation should be performed. In his (Mr. M'Dowell's) three cases the patients were in a moribund condition at the time the operation was performed, and yet they all made perfect recoveries.

Mr. Croly said that some seven or eight years ago he had the honour of communicating some cases of croup to the Society, and a very interesting discussion followed on the treatment of croup on that occasion, amoug the speakers, he remembered, being the late lamented Dr. Beatty. He (Mr. Croly) confessed, whether it was owing to the teaching of the professors who had gone before them or not he could not say, but he had become prejudiced against the operation, and had, he might say, given it up in cases of croup. He did not say that he was so opposed to the operation of tracheotomy that he might not by-and-by come round to it again; he merely stated that at present he was very strongly opposed to it. When he spoke from his own small experience in the treatment of croup, he thought nearly every hospital physician and surgeon would agree with him in saying that they did not get many cases of croup in hospital practice, not, at all events, in proportion to the cases met with outside. In connection with his experience at the old Sick Poor Institution in Meath Street for the last thirteen years—as he had no notes he was obliged to rely on his memory—he found that the cases of acute tracheitis recovered under the ordinary treatment, while the cases operated on all died. He did not say that if he had operated on these cases earlier he might not have had a fair number of successful cases. The difficulty to his mind was, what cases of croup should they operate on, and when should they be operated on. If a surgeon was sent for to see a child in acute croup, and recommended, as Trousseau recommended in tracheitis, immediate operation, he (Mr. Croly) did not think he would be justified in making such a recommendation, even if the operation could be performed. There was certainly one great difficulty to be met with in these cases, and that was the great mortality in tracheotomy as an operation. Certainly, as far as his own experience went, he looked upon tracheotomy as one of the most fatal operations in surgery. He wished now to allude to a paper to which his attention was drawn some years ago—a paper published by Mr. Whittle, of Liverpool, who had written a very able communication on this subject. Dr. Whittle divided croup into seven varieties, but they might dispense with five of these for all practical purposes He (Mr. Whittle) stated that the mistake generally made was to describe acute croup as false croup, and in mixing up false croup with an intense form of tracheitis without false membrane. Mr. Whittle did not recommend the operation of tracheotomy in cases of croup where there was a deposition of false membrane, but he recommended tracheotomy to be performed where there was intense tracheitis without false membrane. He (Mr. Whittle) formed a diagnosis as to the existence of false membrane upon the patient having premonitory hoarseness for three or four days before the croup was set up. Unfortunately, in the two cases of tracheotomy and the case for tracheitis without false membrane that Mr. Whittle alluded to in his paper, he had had an opportunity of a post-mortem examination in each case. With reference to the treatment of the French surgeons, Mr. Whittle made an observation as to whether the dry climate of France might not have a good deal to say to the formation of false membrane. With regard to false membrane, they had had in this country, Ireland, cases where children recovered with a false membrane coughed up. He (Mr. Croly) had presented to this Society a beautiful specimen of a false membrane in a case of croup coughed up by a child. It formed a perfect cast of the trachea. False membrane was, however, subsequently reproduced, and the child eventually died. He could not understand if tracheotomy was performed for a false membrane why the false membrane might not be reformed. He could mention a number of cases where there was no pulmonary congestion and the air freely entered the lungs; but still the children died. He had tried every treatment. If the surgeon was sent for to see a case of acute croup within the first hour he (Mr. Croly) considered that it was not at all an unmanageable disease if they gave emetics, hot applications to the throat, and such treatment as that, without going in for heroic remedies. When a boy, he had seen his father open the external jugular vein in a case of croup, and he had opened the external jugular vein himself. He therefore thought croup in its early stages was a curable disease. Unfortunately, in hospital practice they got cases of croup brought in in the last stage, and the question then was, were they to cut the child's throat, and then, if the operation failed, be told by the parents that it killed the child. He saw one case in the dispensary in which the child was gasping and evidently dying. He told the parents there was only one chance for the child, and he opened the windpipe—the high operation—in the dispensary, and the child rallied for a while, but subsequently died. Mr. Croly said, in conclusion, that he must confess that, as far as his own experience went, he was opposed to tracheotomy in croup.

Dr. Henry Kennedy said it appeared to him unfortunate that statistics should ever have been brought to bear on the treatment of disease. He thought every case should be treated on its own special merits, and that a thousand figures on one side ought not to alter what they had to do in a specific case. In this particular disease it had always appeared to him as if it was far more a general disease than what was commonly thought. Nine out of every ten cases that he had seen had been all more or less complicated with not merely a roughness of voice, but with bronchitis or pneumonia—generally speaking, bronchitis—and he thought the whole question of "operation or no operation" mainly turned on the question of whether bronchitis had preceded an effusion into the trachea or not. Any experience that he had had had shown him that the disease was commenced more insidiously and more gradually than what was commonly supposed, and when the cough of croup was first heard, that the disease, as a general rule, had gone on for four or five days before that cough was heard. He was aware of a very remarkable case that Dr. Corley had recently shown at the Pathological Society where the effusion was entirely confined to the rima glottidis. He (Dr. Kennedy) could only explain that by the possible fact that the other effusion had been thrown up previously. In coming to a determination as to operation in these cases, that should mainly turn in a great degree on the state of the lungs. If there be signs of mischief there he thought they should decline to operate. Supposing, however, that they could ascertain that the lungs were healthy, then, he said, they should operate. He believed, as a general rule, the cases did not hold out a prospect of success, but he nevertheless did not say that the operation should not be performed. One treatment was the use of anodynes. Spasm had a great deal to say to these cases, and hyoscyamus, belladonna, and hydrate of chloral might be used in these cases. He believed them to be important where operation was out of the question.

Dr. F. T. PORTER said that as the name of his uncle had been mentioned in the course of the discussion, he (the speaker) would say that he thought that if his uncle were now alive his opinions would be strengthened, because he (the speaker) thought the constitution was less able to bear the operation of tracheotomy now than it was in his uncle's time. The disease was more asthenic. With regard to the French treatment, it should be borne in mind that the French constitution and climate were different from what they are in this country, and he thought both these had a considerable influence in modifying results. With regard to the treatment of croup, he had met with some bad cases in dispensary practice, and he always found that tartar emetic, with hippo and sinapisms to the feet, and ice over the trachea and chest—he believed that that treatment was an important mode of disengaging the false membrane. He thought that blood-poisoning might very often be the cause of death in cases of false membrane, and was of opinion that if there was a sufficiently roomy incision made there could be no necessity for the tube.

Dr. DARBY said he had in two cases operated unsuccessfully in croup, and the post-mortem examinations in those cases showed that a lymphy deposit had gone down into the smaller bronchial tubes. The reason he rose to address the meeting was because he desired to ask a question—as to the period at which the operation ought to be performed when advocating an early operation. They all knew that a great number of cases of croup were treated successfully by leeching. For his own part, he had very much followed the doctrines laid down by the late Dr. Colles and Dr Cheyne as to tartar emetic, followed by mercury, and he had not found that the disease was more fatal in effect than other very acute diseases might be expected to be. With regard to the operation, he should hesitate to operate on a child whose face was red, and whose pulse was strong. He did not think he would be justified in resorting to a dangerous operation where the case would hold out a reasonable prospect of success by leeching and those other remedies he had mentioned, and where he thought medical treatment would save the child's life. The cases he had operated upon were *in extremis*, where everything else had failed, and he thought he was justified in resorting to the operation. The post-mortem examination, however, showed him the futility of the operation, because the lymph had gone down into four or five branches of the bronchial tubes, and had absolutely choked the child, where no operation nor anything that human skill could accomplish would be successful in saving life. His reason, as he before stated, for addressing the meeting was that when Mr. Thomson replied, that he might be able to indicate at what period he would recommend the performance of the operation, because he (Dr. Darby) would hesitate to perform the operation until the very last moment.

Dr. FRY desired to thank Mr. Thomson for the valuable paper he had read on the advantages of tracheotomy in severe cases of croup. There were some anatomical advantages possessed by the high operation over the low operation that he feared were too often overlooked—he referred to the position of the left inferior thyroid vein, which, passing from left to right from above downwards, crossing the trachea obliquely just above the manubrium to terminate in the left vena innominata, injury to one of which veins, owing to its close connection with the vena innominata, had been ascribed as the cause of death of a patient of Mr. Holmes, in his last work on surgery, and to avoid these vessels Sir Chas. Bell performed the high operation on Sir Thomas Watson's patient. There was a further difficulty to the surgeon in the low operation occasioned by the divarication of the layers of the suprasternal cervical fascia as it split to enclose the manubrium, leaving an interspace of about a quarter of an inch, the coalescence of the layers occurring about half-an-inch superior to the sternum; it therefore cannot offer a difficulty in the high operation. But the immense majority of cases of croup were treated medicinally at home by the mothers without or with but little professional assistance. In the manufacturing districts of England each mother kept a small bottle of balsam of copaiba, which experience had taught her was a reliable remedy in even the most severe cases. They gave it in small teaspoonful doses repeated at short intervals. He regretted that in Ireland that drug was never prescribed in these cases, having as an assistant compounded prescriptions north, south, east, and west of Ireland, and he had never once known it to be prescribed in such cases. He would be glad to learn from Mr. Thomson what remedies had been prescribed prior to deciding on operating in the cases mentioned in his paper—the drug, the dose, and how frequently had the dose been repeated.

Prof. BENNETT said that there was one observation which had been made in the course of the debate to which he desired to address himself, and that was the observation in which Mr. Croly took such a gloomy view of the operation of tracheotomy in general. He did not think that the statement would be generally endorsed that tracheotomy *per se* was an extremely dangerous operation. Speaking of his own experience, he could boast a success in six out of seven cases, and even in the seventh that death was not from the operation of tracheotomy at all, but from diarrhœa ten days afterwards. He knew that that was perhaps an exceptional success, but he thought that both abroad and at home the operation of tracheotomy *per se* as applied all round to cases for which it was applicable was not to be regarded as a very dangerous operation. Even in very young children many surgeons present knew that it was an extremely favourable operation in cases in which the children suffered from scald of the glottis. In such cases he had seen and had the very best results himself. Another point he would wish to refer to, and to which Dr. M'Dowell alluded, was the great advantage of the high operation, especially in very young children. His (Dr. Bennett's) own experience—perhaps accidentally acquired—went even further than Dr. M'Dowell's, and in every case in which he (Dr. Bennett) operated—except in one—he entered the knife first through the crico-thyroid membrane and passed it down through the cricoid cartilage and then through the upper rings of the trachea. He saw no reason to change that. There was only one thing as far as his experience went in these cases, and that was the increased difficulty in inserting the tube in consequence of the stiffness of the cricoid cartilage. Every one of his cases were operated on in an emergency, in fact, a few minutes more would have completed the life of any of the children, and the greater number of the cases were performed by candle-light, and with the assistance only of a couple of students. So that the advantage of the high operation, so far as those cases went, was unquestionable, and the only objection he could see to it was the difficulty, which was certainly a prominent one, of introducing the tube in consequence of the resistance of the cricoid cartilage.

Mr. THOMSON, in reply, thanked the Society for the kind and generous tone in which the paper had been spoken of, and said that at that late hour he would not occupy their time for many minutes. With reference to the observations of Mr. Macnamara as to the statistics of amputations which he (Mr. Thomson) had quoted, he wished to say that they were the statistics which had been collected by Mr. Lane, and they comprised the statistics of the principal hospitals in London. Unfortunately, in the city of Dublin, so far as he (Mr. Thomson) was aware, there was not that complete system of gathering statistics of the results of the operations in the different hospitals that was adopted in London, and possibly—although Mr. Macnamara was able to give a very good report of the result of capital operations of the thigh, &c.—if all the hospitals were able to send in their statistics the results would come to pretty much the same as those they found in London. Mr. Thomson then proceeded to say that he could not follow every speaker who had addressed the Society in the course of the discussion, but he thought it had been asked by several what were the indications which would guide the surgeon in interfering by operative means. He had mentioned in his paper the indications that had been given by Professor Heuter, of Greifswald, who had written most carefully on the subject, and who said that as soon as they observed that the substernal tissues began to sink and that that sinking indicated that the lungs had begun to be engaged, and were not acting as freely as they ought, that was the proper time to interfere. He (Mr. Thomson), in addition to that, would suggest that the physician or surgeon who happened to treat the case medically, as ought to be done in the first stage, should, when he observed the disease running on, carefully watch for those symptoms, when it would be a fair proposition to make to the parents of the child—judging from past experience—that it would be proper to open the trachea. Dr. Kennedy had suggested that one of the contra-indications in case of operation would be the question whether bronchitis had been the primary affection, or that the child had been labouring under some of the symptoms for several days before, and that, if they were satisfied that the lungs were engaged, the operation should not be undertaken. All he (Mr. Thomson) could say was, looking over the ex-

perience of a great number of surgeons in different parts of the world, as they had been collected, that there were several cases reported in which that very question was referred to, and in which they, being satisfied that the lungs were in a condition of inflammation, incipient or otherwise, operated upon the principle that the clear indication was want of air to the lungs, and those cases had recovered. With reference to the remarks of Mr. Croly, he (Mr. Thomson) would like to refer to the point Mr. Croly had made, and which, it happened, had been brought forward by Mr. Whittle, of Liverpool, as to the presence or absence of a membrane in the trachea. Now Mr. Whittle had laid down some rules of diagnosis as to the presence of this membrane, and Mr. Croly stated that he always expected or believed that there was a membrane in the trachea in those cases where the disease came on suddenly at night with urgent symptoms. All he (Mr. Thomson) could say was that Mr. Whittle's experience did not correspond with that of the greater number of writers on the subject, who seemed to think that it was not always possible to indicate whether there was a membrane in the trachea or not, and that the condition might arise as had been stated in Mr. Porter's book. In the early stages there might be so much encroachment of the membrane in the trachea or larynx as to set up these symptoms of inflammation, and cause the death of the child, so that he held that, even in cases where the membrane was not present at all, it would be a justifiable thing to operate as soon as the surgeon saw that there were the usual symptoms of obstruction. He would not now detain the Society any longer, more than to mention one point on behalf of Mr. Croly, which was in reference to an observa- made by Professor Bennett. He (Mr. Thomson) agreed with Professor Bennett that Mr. Croly had given too gloomy an account of the operation of tracheotomy in general. He (Mr. Thomson) had seen a number of cases himself—he had seen five cases of recovery in which the operation was performed in cases of croup. At all events, Mr. Croly wished him to mention that in fourteen recorded cases which happened in London of scald of the glottis in which the operation of tracheotomy was performed, eleven of them died. That was, of course, a very high percentage, and was much more unfavourable than the result of Professor Bennett's operations. In conclusion, Mr. Thomson thanked the Society for the way in which the paper had been received and apologised for any shortcomings in the reply that he had made owing to the lateness of the hour.

The Society then adjourned until Friday, February 4th.

WEDNESDAY, FEBRUARY 9, 1876.

DISEASE GERMS AT HOME AND ABROAD.

In the few remarks on disease germs we last week thought it a duty to place before our readers we could do no more than take a cursory glance at the leading facts in connection with this controversy. Professor Tyndall assumes that his experiments place beyond a doubt the direct and potential agency of the floating clouds of germs in the atmosphere in the production of certain infections and contagious diseases. These germs, although too subtle and minute for detection by the highest powers of the modern microscope, can be traced in their course by the electric lamp, or, in his words, by "the power they possess of scattering a beam of light, and their virulence appears to be relatively in proportion to this power."

Those who have been at the trouble to examine the atmosphere, microscopically and experimentally, can have no doubt whatever that immense quantities of floating particles may be readily detected, and that germs, ova and spores, of bacteria and fungi form no inconsiderable portion of the solid particles in the air of towns, but that it necessarily follows these are the chief agents in the production of disease is, as we submit, yet to be demonstrated. Professor Tyndall affirms that because putrefactive and fermentative changes occur with a rapid development of bacteria, moulds, &c., in his variously prepared infusions, there must necessarily be a parallelism with the progress of infectious diseases, but between the ordinary recognised processes of fermentation and zymosis there exists a wide and important difference, and which has yet to be bridged over before we can accept his theory. Professor Tyndall has evidently lost sight of a fact, pointed out by Dr. Bastian, that, "whereas in an ordinary fermenting fluid the changes initiated by the ferment take place in a mere isolated mixture of organic substances, while in zymotic processes the changes brought about by contagium occur in the fluids and tissues of a complex living body." But have his experiments convinced us that the contagium of infective disease can under no circumstances be originated *de novo*, and do they quite consistently explain what takes place, for instance, in the fatal disease occurring among silkworms (muscardine)? In the blood of these animals the fungoid elements grow and destroy the various tissues of the body. Dr. Klein has discovered similar spores in the blood of sheep, and these, he believes, are the cause of sheep-pox. Muscardine can readily be produced by shutting up silkworms in a glass bottle or box, and by overfeeding them for a time. The animals, when thus affected, are quite capable of spreading the disease to other silkworms, for it is eminently contagious. If we look to sheep-pox itself, the facts at present known are irreconcilable with the notion that the organisms found in the diseased tissues are themselves the cause of the disease. After the first local contact of the contagium with some surface it is subsequently supposed to multiply and be disseminated through the body by means of the blood. On the other hand, it is a well-attested fact that inoculation with the blood of an animal suffering from ovine small-pox does not produce the disease in another animal. "How," asks Dr. Bastian, "can those who believe in the germ theory for ovine small-pox account for this absence of germs from the blood?" In the East a series of experiments have been carefully made, which have a most important bearing on this question. Drs. Lewis and

Cuningham have just presented a valuable report to the Government of India, which goes a very long way to show that in a climate far more favourable to the germ theory of disease, the evidence is most unfavourable to the theory. A series of well-conducted experiments, extending over several years, and undertaken with a view to elucidate the nature of the connection between certain diseases and parasites, particularly growths of a vegetable character, have entirely failed to afford evidence in support of such a doctrine.

First, with regard to the contagium of cholera, Dr. Cuningham has convinced himself that the disease is due to certain conditions of air and soil as yet but little understood, and not to bacteria or the so-called micrococci of Professor Hallier. This for the present disposes of a disease that set the germ theory rolling. Nevertheless opinions have been gaining ground that the lowest forms of vegetable life are endowed with the power of inducing disease. Fortunately for mankind, however, as Drs. Lewis and Cuningham truly observe, nature has set a barrier between spores and germs and organised matter, upon which they may chance to settle, and this barrier is *healthy* life. It has yet to be shown that the tissues of an animal, so long as it retains its vitality undiminished, is liable to succumb to the attacks of spores or germs. In those instances in which it is known that fungi are associated with the existence of disease during life, it is far from proven in any single case that the disease was not present prior to the fungus. There is another barrier to the unlimited development of fungi, and that is the unsuitableness of the soil for its nourishment. Even with regard to animal parasites, this feature is particularly evident, not only with respect to the entozoa, but epizoa, which are limited to certain animals, and even to defined areas of the body. It is not improbable, as Mr. Hogg argued in 1859 (see paper on "Parasitic Diseases," *British Medical Journal*, March 26th), that the morbid secretions resulting from disease furnish the special pabulum necessary for the development of the particular kinds of fungi constantly forming so prominent a feature in animals both before and after death.

Of animal tissues none are more frequently affected by fungi during life than the bodies of insects. Flies, beetles, bees, silkworms, &c., when affected by fungi are found, when examined after death, to have been permeated t hrough and through by mycelial threads; this would certainly be more significant could it be placed beyond a doubt that the tissues were not diseased before the advent of the fungus—"that the fungus did not follow the disease as the roots of a plant creep towards a stream." One of the most remarkable of the supposed fungoid iseases occurring in the human being is the so-called Fungus-foot disease of India," and this has received no inconsiderable share of attention, from the time Mr. 'Godfrey, of Madras, first published an account of the disease in 1844 to the present moment. Dr. Vandyke Carter attributes the disease to the fungoid elements found in connection with particular specimens, and the disease has in consequence received a typical name, "Mycetoma;" but after a series of painstaking and careful examinations Drs. Lewis and Cuningham have come pretty much to the same conclusion Mr. Hogg came to in 1871 (*Medical Times and Gazette*, July 22, 1871, and *Microscopical Journal*, August, 1871)—first, the disease is to be found in two forms, the pale and the dark; and second, that the lesions in both have much in common, but the morbid products are unlike. In the pale variety they are chiefly fatty matters in varied pathological forms; in the other variety the fatty matters are much less abundant, and the dark material which is characteristic of it is almost entirely free from fat. But the most important conclusion arrived at is, that the various bodies which have been regarded as different stages in the development of a peculiar fungus will bear no such interpretation, and that the Madura foot disease cannot be attributable to fungoid origin. The first variety consists almost wholly of fatty matter, oleaginous and crystalline, and in which the amount of thickening in the connective tissue blended all in an incongruous mass partaking of an elephantoid nature without the slightest trace of the presence of fungoid bodies, or of anything save degeneration of the normal elements of the various soft and hard structures of the foot. Drs. Lewis and Cuningham's words are, that "having studied the various stages of the disease, and in all alike has there been an absence of any demonstrable parasites, but, more than this, we have been able to trace out a series of modifications of the elements of the normal tissues terminating in lesions and degenerations which are quite capable of accounting for all the appearances present in the most advanced stages, and which, therefore, render the assumption of the essential agency of a parasite, not merely unnecessary, but even inadmissible." In so far as the common fatty concretions are concerned, it is rather a caution as to the interpretation of phenomena connected with them than any further description we can give here. As previously mentioned, these concretions, under the influence of various reagents, very readily give origin to an abundance of that curious and ill-defined substance which Virchow has termed myeline. A development of myeline is specially prone to occur where portions of the fatty matter, roe-like masses, &c., freshly removed from an alcoholic preparation, are subjected to the action of liquor potassæ.

The multifarious and highly complex forms of tubes, filaments, globules, and cysts which may frequently be observed to become developed, shooting out, and, as it were growing from the globules, and aggregations of fatty matter are wonderful, and such that they could hardly be believed to owe their origin to such process or material were not their development distinctly traceable through all its stages. From the extremely organised nature of their appearance they are peculiarly liable to be mistaken for fungal growths, especially by those who are unused to the practical study of such bodies, and to the various appearances presented by the complex oily compounds, and it is therefore highly necessary that very great caution should be exercised in the interpretation of such phenomena.

We would, however, guard against the inference that no fungoid elements whatever have been discovered in connection with the Madura foot, for in a less frequent form of the disease, shown to consist of degenerated tissue, mixed to some extent with black pigment bodies, fungus filaments have been found, and separated after maceration in liquor potassæ; but as these threads con-

tain no plasma and possess no vitality, they can scarcely be said to have a pathological significance—indeed, Drs. Lewis and Cuningham emphatically assert that, not only does "*Chionyphe Carteri*" not cause the disease, but that it cannot be developed from the fungoid elements contained in the morbid products.

THE CRITICISM OF THE VISITORS ON THE DUBLIN UNIVERSITY EXAMINATION.

THE Report of the Visitors appointed by the General Medical Council to inspect the examinations of the University of Dublin was, it may be remembered, not altogether laudatory, though generally very favourable, to the system of examination carried out by the University. The Professors and Examiners made, therefore, to the Board of Trinity College some time since a replication to the criticisms of the Visitors, and this answer has been approved by the Board.

In the first place, the Visitors object to the mode of voting on the pass or rejection of the candidate at the Half M.B. Examination.

"If the two Examiners agree in their judgment of the candidate's fitness or unfitness, no discussion respecting it takes place; but should they differ in opinion, the question is referred to the whole Board, which, upon due consideration, determines by a majority of votes what the verdict should be.

"We may be allowed to remark that this mode of proceeding appears to be open to the objection that the question is determined, in part at least, by the voices of some who, possibly not having any special knowledge of the subject, must be guided by more or less vague and undefined considerations; so that to us it seems hardly possible but that occasionally some inequality in the judgment given must arise."

The Professors and Examiners dissent *toto cœlo* from the foregoing criticism, and are of opinion that when the two Examiners differ in opinion as to a candidate, nothing can be fairer than to constitute the remainder of the Court of Examiners into a kind of jury, before whom the Examiners plead their cause, for and against the candidate.

The principle adopted by the Visitors is, it seems to us, sound and in accordance with the modern systems of examination. It is the object of those systems, as far as possible, to eliminate the "jury" system of which the Professors and Examiners approve, and to substitute for the vague impressions upon which it was formerly usual to form a verdict, a system of separate marking by the Examiners according to the actual answers given, and not according to their personal estimate of a candidate's style.

Secondly, the Visitors give expression to a protest against the refusal of the Board to hand over the written answers of candidates to them,—

The Professors and Examiners (16 in number), thereupon again positively and unanimously confirm the resolution, for the same weighty and honorable motives that influenced their adoption of it originally:

and we entirely concur with them, and, disapproving of the use made of such papers in the reports of other Visitors, we hope that the medical authorities will continue to regard these papers as, in some sense, confidential.

Thirdly, the Visitors object that—

"As regards Materia Medica, that candidates are not required to produce evidence of having received any instruction in Practical Pharmacy, although the Professors are anxious that a change should be made in this respect."

After mature deliberation, the Professors and Examiners have decided by a majority of votes that it is not expedient to recommend the Board to introduce Practical Pharmacy into the curriculum for the M.B. Degree.

In dealing with the M.B. Examination, after a reference to apparent eccentricities in the marking of answering by the Professor of Medical Jurisprudence which are explained by him in a letter to the Board, the Visitors pass on,

Fourthly, to criticise the constitution of the Court of Examiners.

"It will be noted," they say, "that in each of the subjects of this examination the candidate is submitted to only a single Examiner, who is in all cases a teacher in the College. It was explained to us that as no one Examiner had the power of rejection such as is exercised by the two Examiners in each subject in the previous examination, who, if in accord, can reject a candidate, the latter had so far a security against individual caprice, that the judgment was given by the Board collectively. Still it might, on the other hand, be argued that a candidate may in this way pass, who is altogether deficient in some one subject."

In reference to this remark, the Professors and Examiners admit the weakness of their system.

Surgery and Midwifery, they say, however, are departments of professional knowledge second only to Medicine, and it is possible for a candidate to obtain the Degree of M.B. who is somewhat deficient in Surgery or Midwifery. This is *à fortiori* possible in the University of Cambridge, where neither Surgery nor Midwifery (perhaps rightly) forms a portion of the examination for the Degree of M.B. This defect in our examination (if it be one) is of small consequence in Surgery, as the candidate has to pass a special surgical examination for the Degree of M.Ch.

The Professors and Examiners are *unanimously* of opinion that the defect as to Midwifery in the examination for the Degree of M.B. should be met, as in Surgery, by the institution of a Degree in Midwifery—say Master in Midwifery, M.A.O. (*Magister in Arte Obstetricâ*), this Degree to be conferred upon Bachelors in Medicine only, after a special examination before an University Court of Examiners in Midwifery.

The Professors dissent from the remedy proposed by the Visitors—*i.e.*, to associate with the Court a second Examiner in each subject—as they hold the opinion that proficiency in Medicine, Surgery, and Midwifery should be tested by separate and special examinations in each subject: and that it is the duty of the University to provide such tests within its own walls.

The only part of either of the University Examinations with which the Visitors find fault on the ground of the want of education of candidates is with reference to their deficiencies in operative surgery.

"It cannot be denied," the Visitor says, "that on the occasion when I was present, the operative skill displayed by some of the candidates was by no means remarkable, or that they would not have been better for a little further training in such an important part of the profession in which they were aiming to take so high a Degree."

This criticism was referred to Dr. Bennett, Professor of Surgery, who is responsible for the training of the College students in Operative Surgery, and a statement by Dr. Bennett in reference to it was submitted to the Board.

The Professor's defence seems to us less creditable to him than was the Visitor's censure, being neither *ad rem* nor even expressed in dignified language. Mr. Bennett does not seem to deny that the candidates were deficient in their knowledge of operative surgery, but endeavours to exculpate himself and the Examiners by saying that, if ignorant, three out of fifteen of them were rejected. Whatever credit this fact may be entitled to as an answer must be given to the Examiners, not to the teacher who allowed such candidates to present themselves.

Dr. Bennett states that four of the fifte en candidates

above referred to were not educated in this branch of study in Trinity College, and that these four included the three worst answerers in the subject; but the Visitors did not restrict their statement to the rejected candidates, but pronounced a general opinion, in which Dr. Bennett's course of instruction was specially involved.

In view of these facts Dr. Bennett only makes his case worse when he indulges in language like the following:—

"The passage is either meaningless, inserted to fill up the Report, or it is intended to cast an injurious reflection on Trinity College. If such is its meaning, I beg to remark that the Visitor has exceeded the limits of his appointment under the General Medical Council, and assumed the authority of an Inspector of Trinity College."

The Visitor is, in fact, an inspector of Trinity College as far as the deficiencies of her school are manifested in the examination, and he is perfectly authorised to call Dr. Bennett to account for those deficiencies in common with other teachers of operative surgery in Dublin.

The answers of the Professors and Examiners (with this exception) seem to us conclusive; but they have overlooked the greatest flaw in the Dublin University Examination—*i.e.*, that they are conducted mainly by the teachers in the School of the University. A test, however well intended or carried out, can never give satisfaction to the public as long as the student is examined, as he inevitably is, on the "tips" or personal hobbies of the teacher from whom he is learned. Such a system does not commend itself to our sense of justice either as regards the student, the other medical schools, or the public. Before the time for another visitation comes round we trust that the Medical Registrar of Trinity College, whose recommendations have always been marked by judgment and liberality, will see the propriety of suggesting to the Board the appointment of a really independent Court of Examiners.

ARMY MEDICAL REPORTS FOR 1873.

It is to be regretted that these Reports on the Health of the Army are exactly two years behind their time. This takes away much of the interest of the present volume, which contains several valuable statistical and scientific papers.

Out of an average strength of 88,957 men, were 67,541 admissions to hospital and 699 deaths; 3,334 men were constantly sick, which yielded the following percentages of admissions and deaths:—

Admissions	75·92
Deaths	·78
Constantly Sick	3·74

The admissions ranged chiefly under the headings constitutional, digestive, urinary, cutaneous, and accidental diseases. Only twenty-one surgical operations were performed. Continued fevers were slightly more prevalent and fatal than in the year 1872. Of the admissions from fevers—

1,095	are returned as	Febricula.	
641	„	„	S. C. Fever.
128	„	„	Enteric Fever.
5	„	„	Typhus Fever.

Dublin and the manufacturing towns showed the highest death-rate from continued fevers. The ratio per cent. of admissions for syphilis is 8·76 lower than in 1872. The ratio per cent. of men constantly sick from primary venereal sores was nearly double at the stations not subjected to the Contagious Diseases Act as compared with the stations under the Act. 8,166 admissions for gonorrhœa took place during the year, or a ratio of 9·06 per cent. in stations under the Act, and 10·50 in those not under the Act.

Among infantry regiments the ratios per cent. of admissions, deaths, and invaliding in the United Kingdom was—

Admissions	63·73
Deaths	0·80
Invalided	2·42

The lowest death-rate in any infantry regiment was in the 34th Foot, ·12 per cent., while stationed at the Curragh and Dublin; the lowest invaliding rate in the 26th Foot, ·3 per cent. The 90th Light Infantry, stationed at Aldershot and Dover, had the highest ratios of admissions, deaths, and invaliding.

Of 24,895 recruits examined, 7,559 were reported as unfit for the service. Ireland only furnished 3,261 recruits, a third of whom were rejected. Syphilis, muscular tenuity and debility, diseases of the eyes and eyelids, heart, veins, and malformations of the chest, were the principal causes of rejection.

In Bengal, out of an average strength of 37,146 European troops, were 49,589 admissions to hospital and 596 deaths, representing the following ratio per 1,000:—

Admissions	1335·00
Deaths	16·04

Materially lower than in 1872. The febrile and digestive group accounted for the largest number of admissions.

The highest ratio of admissions was at Thausi and Meean Meer. The ratios of admissions and deaths among infantry regiments in the command were—

Admissions	1300·00
Deaths	15·79

The Appendix to the volume contains papers by Professor Parkes, an account of the Ashantee Campaign by Mr. Anthony Home, and contributions by Surgeon-Majors Porter, Gore, Bleckley, and Surgeons Fleming, Page, Nicholson, Douglas, Dick, Welch, Ash, Lewer, Dobson, &c.

Notes on Current Topics.

The Equity of the Adulteration Question.

When the Fraudulent Trading Protection Bill (otherwise known as Mr. Sclater-Booth's Sale of Food and Drugs Bill) was before Parliament, it will be remembered that we contested with all our influence the proposition to legalise facilities for the cheating of the public by unscrupulous tradesmen. We resisted the protection of adulteration on the simple principle that consumers should in all fairness be honestly informed as to what they were asked to buy and should form their own judgment without being deceived as to whether they would purchase or not. This theorem was considered by the *Pharmaceutical Journal* and other trade organs a monstrous proposition, and arguments why the public should be left in ignorance were

abundantly forthcoming. We are pleased to observe that the *Times*, though late in its expression of opinion, accepts our principle to the fullest extent. In the course of a well-known article on "Silent Whisky," published last week, we find the following :

"It seems manifest that a sound Adulteration Act, although it might not prohibit the proceedings which we have described, would prevent the public from being deceived by them. If there are consumers who like to drink silent spirit, variously flavoured, we see no reason why they should not be indulged. Our view goes no further than that such artificial compounds, however delectable in themselves, ought not to be sold under the name of whisky, but under a name or names which should truly express their nature. We all admit that the interference of legislation with trade is undesirable, and that it should at best be regarded as a necessary evil. Notwithstanding this, laxity must stop somewhere, and it may as well stop short of encouraging misrepresentation and deceit."

It is to be sincerely regretted that the *Times* did not give utterance to these words when the Adulteration Act was under debate in the House, and when its great influence exercised in favour of the honest trader and the uninformed consumer would have been of vital importance. It held its editorial tongue, and consequently, the shop-keeping interest in the House of Commons was enabled to carry through a measure which we must characterise as one of the most nefarious means of procuring impunity for trade dishonesty which has ever been adopted by a Legislature.

The Fever Dens of London.

THE wise and beneficent action of the Government last session continues to produce most excellent results ; already much has been done, but much remains, and the authorities of the City of London, guided by their medical officer, are not behindhand in their anxiety to make London what it should be.

A deputation from the Commissioners of Sewers had an interview with the Home Secretary, at the Home Office, on Thursday last, with reference to the approval of one of the 21 schemes for removing the nests and fever dens within the jurisdiction of the Commissioners in the City of London under the powers given them by the Artisans Dwellings Act.

Mr. Cox, as Chairman of the Commissioners, having expressed the gratitude of the citizens for the opportunity of dealing with those plague spots which they believed to exist in the City of London, remarked that they had before them no less than 21 schemes dealing with property in the City of London. Owing, however, to the short time since the Act had passed, and the natural difficulties that arose, they could only ask approval to one plan which had been prepared in time to satisfy the standing orders of Parliament as to notices, &c. Their medical officer (Dr. Sedgwick Saunders, in whom they had every confidence, he having held his position for 25 years) took a very enlarged view of the Act, and he embraced in his schemes everything that was more or less objectionable in the City of London, and that rather militated against having more than one scheme ready, although they generally approved of the whole of their medical officer's schemes. The property the authorities proposed to deal with was of the very worst class as far as sanitary arrangement was concerned. So soon, however, as it became known that certain properties were in their scheme, it had been let under certain conditions which might have the effect of raising the amount of compensation to be paid ; and he submitted that when they were discharging a duty of that kind some protection should be afforded.

The Home Secretary, of course, promised nothing until he had consulted his colleagues ; he, however, congratulated the City of London upon the promptitude of its action, mentioning that the Metropolitan Board of Works and the authorities of most towns had already taken the initiative.

Health of Kensington.

DR. DUDFIELD, the medical officer of health for Kensington, in his report, refers to the high rate of mortality from zymotic diseases in Brompton, and remarks that most of the deaths occurred in well-to-do families. He concludes that the cause of at least one fatal case of diphtheria in the town district was the insanitary condition of the house in which it took place. There were two water-closets in the centre of the house, and ventilating into it. The large water cistern in the roof was found uncovered and in a filthy condition, while the cistern in the basement, principally used for domestic purposes, was found to contain the wings of hundreds of cock-roaches, whose bodies had been slowly macerated and consumed by the household. In all probability these cisterns had not been cleansed for years. The larger cistern, moreover, was evidently in direct connection with the soil-pipe through the waste-pipe. The house was in a new and fashionable locality, and there was no reason to suppose that the state of affairs described was by any means exceptional.

The mortality for 1875 was 19·4 per 1,000.

1,200 children died under the age of 5 years, equal to 43·4 per cent. of the total deaths.

Three deaths were certified by individuals not qualified practitioners.

"The Mysteries of Dentistry."

THE following case, recently tried at the Bloomsbury County Court, goes to show that there are more "mysteries" in some of the departments of dentistry than are dreamt of in the philosophy of the learned writer in the *Daily News*, upon whose lengthy and magniloquent article under this heading we had occasion to comment in our last issue :—

The plaintiff was Mr. Jones, a dentist, of 57 Great Russell Street, Bloomsbury ; the defendant, a purchaser of wardrobes, of 24 Park Row, Chelsea ; and the claim was for £15 15s. for a set of artificial teeth.

According to the evidence of plaintiff's foreman and secretary, defendant ordered the teeth in question, and signed the agreement produced, but after they were sent home she refused to pay for them on the ground that they did not fit. She at first objected to the sum charged, and offered £10 10s.; and when plaintiff ultimately agreed to accept this, she lowered her offer to £6 6s., but this she afterwards refused to pay.

Defendant said she went to plaintiff for the purpose of having a tooth extracted, but he advised her to have

some others taken out, and he extracted seven in all. He then placed some wax in her mouth, and almost before she could be aware of what he was doing he had taken an impression of the gums. He then advised her to have a set of artificial teeth, but would not tell her what the cost would be beyond saying "they will not be much." She ultimately offered to pay £6 if the teeth were properly made, and it was distinctly understood that the plate was to be pure gold. She was led to a desk by plaintiff, and told to sign her name on a blank form at a spot indicated by him. When she found the teeth would not fit she returned them. She wrote a letter offering to pay £10 for the teeth if they were made to fit, but after finding the plate was not gold, she declined to have them.

His Honour said it was a most unusual thing to draw seven teeth at one sitting, and he did not believe it would be possible to take a correct model of the mouth after such an operation, and whilst the gums were swollen and lacerated. He was perfectly satisfied that the plaintiff did not use reasonable skill in the exercise of his profession, and that the teeth never did fit. He was also satisfied that the agreement was for the plate to be of gold, and the charge of fifteen guineas for the set of eleven teeth warranted that supposition. With respect to the order or agreement, which defendant had sworn was not written when she signed it, he should give no opinion, because the plaintiff's reputation was at stake upon it, and he was not present, but he should give judgment for the defendant, with costs.

Metropolitan and National Nursing Association for providing Trained Nurses for the Sick Poor.

This association, the first meeting of which took place last week, has for its objects to train and provide a body of skilled nurses to attend the sick poor at their own homes, and to establish a training school, in order to raise the standard of nursing. It has commenced under the most distinguished patronage, and there is no doubt that it will be a success. Already five lady nurses are working among the poor in connection with this association, and the number will be at once increased. The lady nurses go from house to house, dressing the wounds or otherwise attending the sick, introducing cleanliness, tidiness, and so directing hygienic improvements in some of the filthiest neighbourhoods of London. They act only under the direction of the parish medical officer, or other medical attendant, and prepare a report according to a given form. We shall revert to this subject next week.

The Royal Free Hospital.

We are glad to observe the flourishing condition of this excellent charity. At the annual meeting holden last Thursday, the report of the committee of management showed that during the past year the receipts from all sources amounted to £7,916 5s. 9d. The balance at the bankers at the close of the year was £2,504 16s. 9d., and the amount of the Government stock, temporarily held by the trustees, and available for general purposes, was £2,166 13s. 4d. It was a subject of regret that an unusual number of cases of erysipelas had occurred in the hospital during the past year, but the committee had ascertained that such cases have been common at most of the London hospitals. The working of the hospital remained satisfactory. It had been intimated by Mr. George Moore that he intended to found a convalescent home for the reception of patients from the Royal Free and St. Mary's Hospitals. Nearly the whole of the late Mr. Milne's estate had been realised, and the accounts would shortly be closed, when the hospital would come into possession of about £9,000. Mr. Frederick Gant, F.R.C.S., expressed his belief that ere long the hospital would be recognised as a clinical school by the College of Surgeons.

Wholesale Destruction of Fish.

During the past few weeks thousands of dead fish, mysteriously poisoned, have been seen floating upon the river Ravensbourne, a clear country stream near London, until recently the source of the water supply of the Kent Water Works Company. The tenants and owners of fields abutting on the river at once withdrew their cows, sheep, and horses from the land, lest the poisonous influence should extend to them, and considerable consternation prevailed. The parochial authorities of Lewisham, through whose parish the Ravensbourne flows, immediately took action, and ordered an exploration to be made up the stream, with the object of discovering the source of pollution. After proceeding about a mile, and coming to the junction of the Ravensbourne with the river Poole, near Perry Farm, the exploring party found that the Ravensbourne beyond the junction became suddenly clear, and that the water of the Poole was like lime-wash, emitting a horrible sulphurous smell. Attention was then directed to the Poole, and two miles further (in the parish of Beckenham) the explorers discovered a trench communicating with the brick-fields of Mr. Gascoyne. Along this trench was discovered flowing the watery portion of a large quantity of refuse lime carted from the Crystsl Palace Gas Works for the purpose of filling up a pit in the brick-fields, and which in this way found its way into the Poole, thence into the Ravensbourne, subsequently into Deptford Creek, and finally into the river Thames. The refuse lime was found to be largely impregnated with gas and sulphur, and on becoming dissolved in the water of the Poole converted the oxygen necessary for the life of the fish into sulphuretted hydrogen, a poisonous and offensive compound. The man at the brick-field who made the trench, when told of the full extent of the mischief he had thoughtlessly caused, immediately sent a letter of apology to the Lewisham Board of Works, and the Crystal Palace Gas Company have promised to send their refuse lime into Essex in future.

Exhumed Pigs in the Meat Market.

Ellis Greenwood, a pork-butcher at Bradford, who dug up the carcases of some pigs which had died of *typhoid fever*, and disposed of some of the meat for human food, was tried by the West Riding magistrates and committed to prison for two months. He may congratulate himself upon the lenity of his sentence, but we

question whether he will again find customers in Bradford who will give him the opportunity of repeating an act at once so inhuman and loathsome.

Artisans' Dwellings.

THE Board of Works has received from the engineer and superintending architect for the improvement of Holborn, under the powers contained in the Artisans' Dwellings Act, a report showing that it is intended to provide a thousand tenements of one room. Each room is to be provided with a recess for a bed. It is not the intention of the Board to build, but they are ready to offer the land on easy terms to persons who may be willing to undertake the building. As artisans' dwellings companies have hitherto paid a fair percentage on the money invested, besides carrying out a work of philanthropy, it is not probable that there will be any difficulty in disposing of the land.

Conviction under the Contagious Diseases (Animals) Act.

A GENTLEMAN residing in Clapham Park was summoned on behalf of the Metropolitan Board of Works, charged with having failed with all practicable speed to give notice to a police-constable of the fact that he had certain animals (five heifers) in his possession, or under his charge, affected with foot-and-mouth disease, the failure in question being contrary to the provisions of the Act and the order in council. Evidence was adduced showing that five heifers belonging to the defendant were suffering from foot-and-mouth disease, and that the defendant had not given notice to the police as required. The defendant urged that he had been out of town, and that it was his intention to give notice to the police, but he had not had time to do so. He was, however, fined £5 and 14s. 6d. costs, the magistrate remarking that to stamp out the disease it was of absolute importance that notice should be given to the police the very moment the disease was discovered.

Sir Joseph Fayrer, K.S.I.

THE profession will be gratified to hear that Dr. Fayrer has been created a Knight of the Star of India. Sir Joseph has been an indefatigable worker in the cause of science throughout the whole course of his service in the Medical Department of the Army in India, and in consequence of his thorough knowledge of Indian diseases and their prevention he was chosen to accompany H.R.H. the Prince of Wales in his Indian tour.

New Degree in Midwifery in the Dublin University.

THE Board of Trinity College have given their sanction to the establishment of a new degree in Midwifery, which will carry the letters M.A.O. (*Magister in Arte Obstetrica*) with it. In their report to the Board, to which we refer elsewhere, the Professors and Examiners expressed the "*unanimous* opinion that the defect as to Midwifery in the degree of M.B. should be met, as in Surgery, by the institution of a degree in Midwifery—this degree to be conferred upon Bachelors of Medicine after a special examination before a University Court of Examiners."

The Dental Profession.

AN attempt is being made by certain dental surgeons to start a new dental society to which none but those holding recognised qualifications shall be admitted. Some of the objects of the society are "a closer association of the more highly qualified members of the profession, the formulation of an improved code of etiquette, the abolition of that advertising system which does so much to degrade the calling, and generally the elevation of the status and *morale* of dentists" (*sic*).

In the first place, we would remark that it is a pity when a body of gentlemen put themselves forwards as models of professional culture they do not take more care that the language which they use does not contain gross errors in grammar, since such errors may perhaps lead the uninformed to suspect an absence of the superiority to which they lay claim. In the next place, we do not hesitate to say that the new society is quite uncalled for, can do no good, and, on the contrary, must injure the profession by weakening the power of the Odontological Society, which comprises all the eminent members of the profession, and which is doing all that is possible to advance dentistry. We strongly advise the promoters of this new society to abandon their scheme, and instead of holding aloof, to work loyally and heartily in the Odontological Society, to which they and their profession already owe so much.

Ventilation at the Royal Institution.

SITTING among the auditory when Professor Huxley was lecturing at the Royal Institution last week, we were much impressed with the very defective state of ventilation of the lecture theatre, and were somewhat surprised to find that those who undertake to instruct the public in the matter of science and hygiene should be so careless of the health and comfort of their members and friends. We observed on the evening in question ladies led out fainting, and the stifling nature of the air under the gallery almost compelled us to retire. Nevertheless, when an attempt was made to open the ventilators, the downward current set Professor Huxley sneezing, and almost brought his lecture to an abrupt termination.

FOUR medical men have been elected members of the newly constituted French Senate.

WE understand that Dr. Graily Hewitt has been elected an Honorary Member of the Obstetrical Society of Philadelphia.

AT the next Quarterly General Court of the Governors of the Middlesex Hospital, on the 24th February, an Ophthalmic Surgeon will be elected in succession to Mr. J. W. Hulke, resigned.

MR. JOHN BIRKETT, F.R.C.S., Vice-President of the Royal College of Surgeons of England, has just been appointed the Government Inspector of Anatomy of Pro-

vincial Medical Schools, in the vacancy occasioned by the resignation of Dr. John William Ogle.

THE Sheffield School Board, at their last meeting, decided upon a scheme for giving instruction in practical cookery in their schools, and have engaged a Sheffield lady to enter the National School of Cookery at South Kensington to qualify her for giving such instruction.

IT is announced that the examination of candidates for Commissions in the Army Medical Department, which was intended to be held at the London University on the 14th of February next, has been postponed for the present. Due notice will be given as soon as another day shall have been fixed.

IN deference to the views of the Visitors of Examinations, the Board of Trinity College have appointed three "Extern" Examiners—that is, unconnected with the School of Physic, to examine in Medicine. The gentlemen appointed are Dr. Arthur Wynne Foot, Dr. James Little, and Dr. Thomas Hayden.

AT the Clerkenwell Police Court, Mr. John Blackwood was summoned for having conveyed his daughter in a public conveyance while she was suffering from scarlet fever. The defendant said he contracted with the cabman to convey his child to the hospital for 10s., a sum which he at the time considered sufficient to pay for the disinfecting of the vehicle. He was fined £5 and 17s. costs.

THE Medical Society of the College of Physicians, Ireland, will meet this day (Wednesday) at 8 p.m., at the College Hall, when the following papers are set down for reading :—

1. Dr. Finny—"A Case of Dermatitis Exfoliativa."
2. Dr. Hayden—"Biliary Colic."
3. Dr. Grimshaw—"A Case of Abdominal Aneurism."

A SHIP put into Falmouth on Friday with 18 out of 22 of her crew suffering from scurvy. She is the *Royal Sovereign*, of 1,388 tons, from Kurrachee to London, with rape seed. The men state that the meat shipped was very bad. On arrival the medical officer, after examining the crew, ordered them to be sent to the Sailors' Home. Those who suffered most were carried upon stretchers. A Board of Trade inquiry is anticipated.

WE understand that the action against the Pension Medicale of Dublin for damages sustained by a delirium tremens patient in jumping out of a window when incautiously left alone, will be resumed at the next after sitting. On the former trial, it may be recollected, the jury disagreed, declining apparently to recognise the liability of the Pension for the strict custody of the patient under all the circumstances of the case.

A RATHER curious case came on for magisterial decision in London last week, the result of which will not be known for a fortnight. It appears that the parish of Whitechapel have supported for the past three years a female lunatic in an asylum at the expense of about £170. The said lunatic has just had a legacy left her of £100, to which the parish and the husband lay claim. The magistrate thinks, as all sensible men will do, that morally the parish is entitled to the legacy, as the husband has never contributed to her support ; legally it may be otherwise, decision being deferred for a fortnight.

A RETURN relating to drunkenness in Scotland, obtained on the motion of Dr. Cameron, shows that the total number of persons arrested in Scotland for drunkenness during the year ended June 30, 1875, was 61,173, of whom 38,213 were arrested as "drunk and incapable," and 22,960 as "drunk and disorderly." Of the former class 1,106 were arrested between 8 a.m. on Sunday and 8 a.m. on Monday, and of the latter class 1,273. The return also shows that during the year 22,612 persons were taken into custody in Glasgow alone for being "drunk and incapable," of whom 445 were arrested between 8 a.m. on Sunday and 8 a.m. on Monday.

THE Medical Commissionership of the Irish Local Government Board, which has been for so long in contest, has not yet actually been filled, but public rumour gives it to Dr. Croker King. In case he should be appointed, it is expected that the authorities will try to effect a patronage *coup* by appointing a layman to Dr. King's Inspectorship, which would, of course, oust the profession from one of the very few appointments still at its disposal, and would deprive the Irish Poor-law Medical Service of another fraction of the very insufficient medical advice which it now possesses. We hope that every corporation representing the profession will speak out on the subject, for we hear that there is a stripling who enjoys influential connection and who is ready and willing to serve his country in any higher capacity, medical or non-medical, which his friends may get him.

RESIDENT MEDICAL SUPERINTENDENTS OF IRISH ASYLUMS AS CIVIL SERVANTS.

A DEPUTATION consisting of resident medical superintendents of district lunatic asylums in Ireland waited on the Chief Secretary for the purpose of calling attention to their anomalous position in reference to their salary and superannuation.

Dr. Lalor of the Richmond Lunatic Asylum, said, what the deputation particularly desired was that instead of the capitation grant of 4s. per head there should be, in the first instance, an estimate passed for the salaries of the medical superintendents, and that the balance remaining of the grant should be applied to the general expense of the institutions. The result would be that the superintendents would then become Civil servants, and under the 4th section of the Superannuation Act of 1859 the Lords of the Treasury would be entitled to add to their period of service a term not exceeding twenty years, in consideration of the preliminary training the medical men had undergone. It would be seen that this would place the resident medical superintendents in a much more satisfactory position as regarded superannuation. They had every reason to be gratified with the relief afforded by the Government in the capitation grant, and the reason why the deputation suggested that the superintendent should be paid out of the capitation grant was that they were slow to ask the Government to contribute more largely than at present. Dr. Lalor then read a memorial, which stated :—

We are deprived of the benefit of the Superannuation Act of 1859, not being recognised as Civil servants, as our salaries are not paid through the Treasury, and we can therefore only obtain a pension under the Act of 30 and 31 Vict. cap 118,

sec 8., under which Act we must hold office for 40 years in the same asylum before we can obtain two-thirds of our salary and allowances as superannuation, whilst our brethren in England are entitled to the same pension after 15 years service (25 and 26 Vic., cap. 3, sec. 12). That the public service suffers from the present state of the law, as senior men of many years' experience refusethe charge of larger asylums, knowing that by removing from one asylum to another they would forfeit their right to a pensian should the length of their service not extend to 40 years in the lalter. That the Poor-law medical officers of unions in Ireland, who are not appointed by Government, and over whom the Executive have no control, receive half their salaries from the Consolidated Fund.

Sir Michael Beach—You have just reminded me that the Government have been very liberal in their grant to the asylums. What would you suggest?

Dr. Lalor—That in place of the capitation grant being passed in a bulk sum, a certain sum should be put in the estimates for the salaries of the superintendents, so that the superintendents might become in reality Civil servants.

Sir M. Beach—The probable result of the changes you suggest would be that the board of governors being relieved from your salaries would consider it a grievance that they did not receive the same sum for the maintenance of individual lunatics as the English asylums receive. You are really confusing two different things. If it be granted that the scale of pension is not now sufficiently liberal, it is perfectly possible to increase the scale without touching the resources from which the salaries are paid.

Dr. Lalor said the case of the English asylums was one of their strong points. In England, where the local rates contributed three-fifths and the Government two-fifths of the expense, the board of governors had complete control over and the appointment of the superintendents, whereas in Ireland they neither appointed nor controlled them. They were appointed by the Lord Lieutenant, who also made the rules and had the control.

Sir M. Beach said a great deal might be said in both ways on that point; but it has no special reference to the point which, as I understand, you wish particularly to press on me —namely, that the scale of retiring allowances is inadequate.

Dr. Eames said that if a superintendent removed from one asylum to a larger one, he was not allowed to count his previous service. That grievance would be removed if the Government paid the salaries.

Sir M. Beach said that when replying last session to a question on this subject, he stated that he had no evidence of any general feeling on the subject, even among the officers of lunatic asylums, and certainly none among the governors in favour of the proposed change. He had had a great many memorials from grand juries, asking for superannuation for county surveyors, and the whole subject required serious consideration. If an opportunity arose, he would endeavour to improve the condition of the medical superintendents, provided he saw sufficient ground for doing so. He could not give any idea as to the best means of effecting the improvement, nor could he undertake to bring in a special bill on the subject next session. He had had some trouble last session in carrying a bill in reference to lunatic asylums, and he was not aware that any bill would be introduced on the subject on this occasion. He did not suppose this was a matter in which they could legislate solely without reference to other points connected with lunatic asylums.

THE BORDER-LAND BETWEEN ANIMAL AND VEGETABLE LIFE.

At the Friday evening meeting at the Royal Institution of Great Britain, on the 28th ult., Professor Huxley gave a discourse on the "Border-land of Life." He explained that Cuvier's division of organised beings was no longer tenable, neither could he take his subdivision of living beings into *animated*, which possess sense and motion, and *inanimated*, which are devoid of these functions and simply vegetate; although they exhibit certain movements, yet none justify the ascription of perception or will in plants. From the mobility of animals Cuvier deduced their need of—1. An alimentary cavity or reservoir of food; 2. A circulatory system; 3. A complex system of muscles and nerves, including not only the chemical elements of plants, but also nitrogen, which he affirmed to be peculiar to animals; and, 4. Respiration, during which they absorb oxygen and exhale carbonic acid—the relations between animals and plants to the atmosphare being, therefore, inverse. Thus wrote Cuvier in his "Règne Animal" in 1828, his reasoning being sound and true according to the knowledge of the time, and for the higher forms of life. Since that time, especially during the fourth and fifth decades of this century, biological science has undergone a great and rapid revolution through microscopical investigation, and Cuvier's distinctions have fallen away. It has been clearly proved that innumerable plants and free plant-cells pass their lives in an active condition not distinguishable from that of the lower animals, some of which either have no stomach or are all stomach. Nitrogen has been shown to be an essential constituent of vegetable as well as animal matter, and the tissues of plants are quite as chemically complex as the substance of animals; and although green plants by the agency of their chlorophyll, in sunshine, absorb carbonic acid from the air and give off oxygen, yet the reverse takes place in the dark; while fungi, devoid of chlorophyll, absorb oxygen and exhale carbonic acid like ourselves. The researches of Schwann and Schleidin, beginning in 1837, founded the modern science of histology, andprove that the tissues of the fabric of animals and plants are composed of cells closely resembling each other; and the researches of Dr. Burdon Sanderson, Mr. Darwin, and others prove that plants possess contractility similar to the reflex nervous action on which the locomotion of animals depends. Professor Huxley, after describing various interesting experiments relating to the subject, referred to the microscopical examination of an infusion of hay, recently submitted to him by Professor Tyndall, in which, besides wriggling bacteria, which are unquestionably plants, he detected very active monads, in size about the one three-thousandth of an inch, and pear-shaped, which he named heteromitæ. He then adverted to Messrs. Dallinger and Drysdale's researches on a similar creature, commenting on its very rapid multiplication by division and subdivision, thus increasing about a thousand in an hour; and after duly weighing all the evidence he could obtain, and reasoning by analogy derived from the study of the potato fungus and other organisms, which, after much discussion, had been proved to be vegetable, he concluded by acknowledging his utter inability to decide at present whether his new heteromita was an animal or a plant, so that there is still a border territory between the animal and vegetable kingdoms.

LIABILITY OF INSURANCE COMPANIES TO THE INTEMPERATE.

In a recent issue we referred to a case which was about to come before the Master of the Rolls in Ireland, in the form of an application by the National Insurance Company to set aside an insurance upon the life of one of its policy-holders, and it has since been under argument.

The bill stated that on the 30th December, 1872, the defendant sent a proposal for the assurance in writing, which purported to state truly, in the form of answers to printed interrogatories, several particulars respecting his age, health, and habits, and was accompanied by a declaration at the foot of the proposal, to the effect that he was in good health, was not engaged in any occupation nor addicted to any habits prejudicial to health nor afflicted with any disease tending to shorten life, and he thereby agreed that said declaration should be the basis of the contract between him and the plaintiffs, and that if any untrue averment was contained in the declaration all sums that should be paid on foot of such assurance should be forfeited and the assurance void. The proposal stated, amongst other things, that the defendant's habits had been always strictly temperate. The proposal was forwarded to the plaintiffs by their agent at Ballyhaise, county Cavan, with a report, wherein he stated that he had no reason to suspect that the defendant was, or had been otherwise than regular and temperate in his habits; and he also sent

plaintiffs a letter, recommending them to accept the defendant's proposal. A certificate from Dr. Malcolmson was also sent, which stated that defendant was in a good state of health, and an eligible case for life assurance. The statement of Mr. Humphreys not setting forth whether the defendant was of temperate habits, the plaintiffs' secretary wrote to said Wm. Humphreys, calling his attention to the omission, and, in reply, the secretary received a letter, in which he stated that the defendant's habits were perfectly temperate. Believing the representations were true, the plaintiffs issued a policy on the defendant's life for £5,000, and it provided that if anything averred in the defendant's declaration should be untrue the policy should be void. Until after the month of January, 1874, the plaintiffs had no reason to doubt the statements in the declaration, but they then discovered that defendant's habits were not strictly temperate, and had not been for a considerable time prior to his proposal; that by continued indulgence he brought on an attack of *delirium tremens* within a few months after the issuing of the policy. In October, 1874, the solicitor for the plaintiffs wrote to the defendant informing him that the plaintiffs were about to institute proceedings against him for the purpose of having the policy cancelled, and offered to return him the premiums he had paid if he would surrender the policy. The defendant substantially denied that he was or had been addicted to intemperate habits, although he admitted that on two or three occasions since the policy was effected he had suffered from attacks of delirium, which were brought on as much by family disputes as by intoxicating drinks.

In delivering judgment, the Master of the Rolls said that the words "strictly temperate habits" in the policy did not imply that a man was to be a teetotaller or a man who entirely abstained from drink. A man of temperate habits was one who uniformly made a temperate use of intoxicating liquors. For instance, a man at dinner might take sherry and claret and a glass of punch after it. He might do the same at luncheon, take a glass of sherry, or a glass of whisky and water, and in his opinion he would be a man of temperate habits. Under all the circumstances of the case he could not help granting the prayer of the petition, and voiding the policy, with costs.

The issue is one of great public, and not a little professional importance, inasmuch as it raises the question of the possibility of repeated attacks of delirium occurring within a few months of reputed temperate habits, and because it is almost the first case in which an attempt has been made to invalidate a policy upon such grounds during the lifetime of the insured.

THE CERTIFICATE SYSTEM IN DUBLIN.

As we expected would be the case, the King and Queen's College of Physicians has followed the honourable example shown them by the University of Dublin, and has declared its opinion that lecture and hospital certificates must in future represent *bonâ fide* a diligent attendance by the student, and be not simply a receipt for money paid. No other course was open to a college which appreciates its own honour and dignity, and we look for a speedy decision of the Council of the College of Surgeons in confirmation of the same principle. The following resolution was adopted on Saturday last by the Fellows of the College of Physicians on the motion of Professor Haughton:—

"That this College approve the principle that certificates of attendance upon hospitals and medical lectures shall be *bonâ fide*.

FEES FOR CERTIFYING DANGEROUS LUNATICS IN IRELAND.

The Athy Board of Guardians received recently an application from Dr. Percival, of Stradbally, for his fee of £2 (under due certificate of the magistrates) for certifying a dangerous lunatic.

After a short discussion] it was ordered by the Guardians that payment be declined, as the parents of the man were well able to discharge the debt, and that the doctor look to them for payment.

It is to be regretted that there is not some one in the Athy Board possessiug sufficient knowledge of the law to save them from legal blunders of this sort. The 14th Section of the Lunacy Amendment Act of last year distinctly orders the payment of Dr. Percival's fee when duly certified, and the Board of Guardians have no right whatever to refuse or to refer him to anyone else for payment.

If Dr. Percival's claim has not been settled he can enforce it without the least trouble, and a letter to the Local Government Board will probably elicit an order to the Guardians to pay.

A third attempt at election to the Surgeoncy of Swift's or St. Patrick's Lunatic Hospital, in Dublin, vacated by the death of Mr. John Hamilton, took place last week, the candidates being, as before, Mr. Colles and Dr. Thornley Stoker. As on two former occasions, the voting resulted in a tie, and there was no election, and the poll will be again held in a month. We anticipate Dr. Stoker's election.

Literature.

ON MENTAL STRAIN AND OVERWORK.

This interesting pamphlet, a reprint from the *Journal of Mental Science*, was the subject chosen for discussion at the late meeting of the Medico-Psychological Association. The author draws the comparisons between the mental culture required some years ago to obtain distinction and eminence in any profession and that required at the present day. In bygone days the generality of students did not overtask their brains by excessive mental application in any field of intellectual labour, and we are told that beyond the few who devoted themselves to the study of divinity, law, or medicine, there was little mental labour known to the middle class of society in general. The diffusion of knowledge was very slow, and years were wont to elapse before a daring thesis in divinity, a new system of pathology, or a great astronomical discovery found their way into the various seats of learning.

The study now required in examinations is vastly superior and extensive to that of only a few years ago, and special attention is drawn to this fact as proving the extra mental strain which is now required by the large

(a) "On Mental Strain and Overwork." By Frederick MacCabe, M.D., Resident Physician and Superintendent to the Central Criminal Lunatic Asylum, Dundrum.

class of students who earn their living by the sweat of their brow. In former days many of the learned professions could be entered without any examination, and for the public service the most ordinary educational acquirements were considered sufficient.

The high standard to obtain even an ordinary pass at the present day is to be highly depreciated, and as an illustration of this may be mentioned the examination held by the Civil Service, and the University of London, where small boys are submitted to severe mental labour quite inconsistent with their mental powers, and before their nervous systems and physical powers have been sufficiently developed; they are consequently unable to grapple with the numerous subjects required.

The present age is one of extreme premature mental activity and competition.

The two important questions discussed by Dr. MacCabe are—

1st. What are the conditions of modern civilised life producing mental strain and overwork? and,

2nd. What are the symptoms indicative of excessive mental strain?

Our attention is drawn to the great competition at present required in every profession, from the highest to the lowest, as well as to the excessive mental strain in those endeavouring to obtain celebrity by their own exertions. All the professions are overflowing with ardent students coping against each other, and there are countless labourers in the cause and progress of knowledge. In consequence of the spread of education becoming so general, the supply of those who live by brain-work rather than by the toil of their hands exceeds the demand.

Manual labour and exercise is at present regarded too much with contempt, and it is by no means a rare thing to see a brilliant youthful mind associated with a feeble frame and stunted development.

The pamphlet is a very comprehensive one, and is clearly written, the various arguments being distinctly placed before the reader.

Correspondence.

QUACK ADVERTISEMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The profession have again to thank you for your spirited denunciation of that portion of the lay press which still continues to aid and abet the loathsome venereal quacks by giving a place in its columns to the indecent announcements of these malefactors. We have also to thank you for your exposure of the puff system, a system which often consists in an editor adding, for a consideration, his endorsement to the false statements of any quack who has the money to purchase it. With regard to indecent advertisements, a recent decision in the police court would tend to show that their publication may be prevented by law. A Mr. Carpenter, "*medical practitioner*," in the Borough Road, was summoned on January 31 by Inspector Davis for causing a certain bill to be affixed in a public recess vested in the Vestry of St. Mary, Newington. A few days previous a man was found posting bills with Mr. Carpenter's name on them, and as they were of an objectionable character the man was taken into custody. He then gave up a number of a similar character. Mr. Edwin, in defence, said he thought such bills did no harm. Mr. Chance entertained a different opinion. It was an abominable practise, and he should use every endeavour to stop it. He ordered the defendant to enter into his recognisance not to repeat the offence. Surely, Sir, if it be illegal to carry on the "abominable practice" of publishing indecent bills in a urinal, where they are seen only by the male sex, it is doubly criminal to print them in the columns of a newspaper, where they must be noticed and read by numbers of young girls and women. Nor can it be alleged that the language of the quack advertisement in the newspaper is more guarded than that of the bills which are so freely placarded and distributed about the country. The announcements in many of the provincial papers are so direct in their allusions that it indeed may be said of them that he who runs may read.

Yours obediently,

Liverpool, Feb. 3rd, 1876. INDIGNANS.

Medical News.

Vital Statistics.—From the Registrar-General's returns we learn that during last week 6,314 births and 4,115 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 27 deaths annually in every 1,000 persons living. The annual death-rate was 24 per 1,000 in London, 23 per 1,000 in Edinburgh, 29 in Glasgow, and 35 in Dublin. The annual rates of mortality per 1,000 during the same period in the other large towns were—Brighton 24, Sunderland 19, Plymouth 16, Norwich 25, Nottingham 34, Bradford 28, Hull 24, Leicester 25, Bristol 26, Portsmouth 21, Sheffield 22, Birmingham 32, Wolverhampton 28, Leeds 28, Newcastle-on-Tyne 26, Oldham 41, Liverpool 30, Manchester 32, and Salford 41. The annual death-rate from the seven principal zymotic diseases averaged 4·0 per 1000 in these towns, and ranged from 0·0 and 1·0 in Plymouth and Sunderland to 6·5 and 7·5 in Liverpool and Salford. The fatal cases of scarlet fever were excessive in Bradford, Portsmouth, and Bristol, and of fever in Oldham, Sheffield, and Liverpool. Of the 15 deaths referred to small-pox in these towns, 13 occurred in Manchester and Salford, and one in Bristol. In London, the 1,637 deaths included 79 fromscarlet fever, 23 from different forms of fever, 15 from diarrhœa, and not one from small-pox. These 261 deaths from the principal zymotic diseases were 18 above the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 3·9 per 1000.

VACANCIES.

North London Consumption Hospital.—Physician. Honorary. (See Advt.)

Royal Hospital for Diseases of the Chest, City Road.—Surgeon. Honorary. (See Advt.)

Lisnaskea Union.—Medical Officer Brookeborough Dispensary District. Salary, £115, with £15 extra as Sanitary Officer. (See Advt.)

Manchester Clinical Hospital for Children.—House Surgeon. Salary, £80 per annum. Address the Secretary of the Medical Board.

Kent County Lunatic Asylum.—Medical Superintendent and an Assistant Medical Officer. Salary of the former £700, with house; of the latter, £150, with apartments. Applications by letter to Messrs. Beale and Hoar, Maidstone, Kent.

Northampton County Lunatic Asylum.—Medical Superintendent. Salary, £500, with residence, &c. Applications to the Clerk of the Peace, County Hall, Northampton.

St. Mary's Hospital, Paddington.—Assistant Surgeon. Honorary.

Middlesex Hospital.—Ophthalmic Surgeon. Honorary.

Lancaster.—Public Analyst. Salary, £300, with fees extra. Address the Clerks of the Peace, Preston.

APPOINTMENTS.

BARKER, Dr. J. E., Medical Officer, &c., for the Kilcullen Dispensary District of the Naas Union, co. Kildare.

RICE, G., M.B., C.M., Medical Officer to the Chorlton Union Workhouse.
RHODES, F., M.D., L.R.C.P.L., Medical Officer for No. 8 District of the Chorlton Union, Lancashire.
WARD, S. H., M.D., F.R.C.P.I., Consulting Physician to the *Dreadnought* Seamen's Hospital.
WHITEHEAD, T. B., L.R.C.P.Ed., M.R.C.S.E., L.M., Medical Officer for the Duncburch District of the Rugby Union.
WILLIAMS, J. L., M.B., C.M., a Surgeon to the Wrexham Infirmary.

Births.

REID.—On the 4th inst., at 3 Royal Marine Road, Kingstown, the wife of Dr. Patrick R. Reid, of a daughter.
TINDALL.—On the 5th inst., at Rydal Villa, Wickham Park, S.E., the wife of Albert Alfred Tindall (MEDICAL PRESS AND CIRCULAR), of a son.

Deaths.

FINDLATER.—On the 23rd Jan., James Findlater, L.R.C.P.Ed., of Glasgow, aged 27.
HARDINGE.—On the 28th Jan., at Grafton Street, Berkeley Square, Henry Hardinge, M.D., aged 56.
HEATHCOTE.—On the 24th Jan., at Lydiate, Lancashire, Michael Heathcote, Surgeon, aged 85.
JOHNSON.—On the 24th Jan., at Newcastle-on-Tyne, George Brack Johnson, M.R.C.S.E., aged 36.
MANNING.—On the 17th Jan., at Croughton, Northamptonshire, Edward Manning, Surgeon, aged 84.
MASON.—On the 30th Jan., at Lewisham High Road, New Cross, J. D. Mason, L.R.C.P.Ed., aged 30.
MEGGET.—On the 29th Jan., at Winlaton, Durham, Archibald Megget, M.D. (late of West Ayton, near Scarborough), aged 68.
SCHUSTER.—On the 23rd Jan., at Barrow-in-Furness, Edwin Schuster, L.R.C.P.Ed., aged 27.
SCOTT.—On the 29th Jan., at Milton bank, Dunoon, David Scott, M.D.
SWEENEY.—On the 26th Jan., at his residence, Ennistymon, co. Clare, Dr. A. Sweeney, after a protracted illness, aged 69.
VOELCKER.—On the 28th Jan., at University College Hospital, George Henry Voelcker, M.B., M.R.C.S.E., aged 23.

ARMY MEDICAL DEPARTMENT.
26th January, 1876.

THE EXAMINATION of CANDIDATES for COMMISSIONS in the Army Medical Department which was intended to be held at the London University, Burlington Gardens, on the 14th FEBRUARY next, has ceen postponed for the present. Due notice will, however, be given as soon as another day shall have been fixed.

(Signed) W. M MUIR, Director-General.

ADMIRALTY.—Medical Department of the Navy, 9 New Street, Spring Gardens, S.W., Nov. 20, 1875.—Notice of Examination of Candidates for the Naval Medical Service.—Notice is Hereby Given, that a COMPETITIVE EXAMINATION of CANDIDATES for admission into the MEDICAL SERVICE of the ROYAL NAVY will take place at the UNIVERSITY of LONDON, Burlington Gardens, on MONDAY, Feb. 14, 1876, and following days, at Ten o'clock. Candidates must present themselves at this Department for physical examination, at Eleven o'clock, on Thursday, Feb. 10, 1876, when, should they be found in all respects eligible, they will be permitted to appear for examination.

The necessary forms to be filled up by Candidates will be supplied on application to this Department.

A. ARMSTRONG, Director-General.

A VACANCY has occurred in the office of PHYSICIAN to the North London Consumption Hospital, London and Hampstead, by the resignation of Dr. W. Lomas. Candidates (who must be Members or Fellows of the College of Physicians, and Graduates in Medicine of a University) are requested to send their testimonials to the SECRETARY, on or before 1st March.

Office, 216 Tottenham Court Road, W.

MALVERN COLLEGE.

This COLLEGE contains THREE DEPARTMENTS—the CLASSICAL, MODERN, and PREPARATORY LOWER SCHOOL.

Boarding and Tuition under 14, £70; over 14, £90. Non-Shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information, apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

BUTLER'S MEDICAL HALL,
53 & 54 LOWER SACKVILLE STREET,
DUBLIN.
ESTABLISHED A.D. 1817,

For Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of
WILLIAM STARKEY, M.D.,
Licentiate Apothecary.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD.—There is a VACANCY for a SURGEON to this Hospital, through the resignation of Mr. Alfred Cooper, Applications, with Testimonials, to be forwarded to the Secretary, at the Hospital, on or before MONDAY, FEBRUARY 28th.

C. LOWTHER KEMP, Secretary, &c.
January 28, 1876.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

LISNASKEA UNION.
BROOKEBOROUGH DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—In consequence of the lamented death of their Medical Officer, Dr. Wilson, the Committee of Management of the above Dispensary District will, at their Meeting to be held on TUESDAY, 21st MARCH, 1876, at the hour of 12 o'Clock noon, proceed to elect a duly-qualified Medical and Sanitary Officer for the District, at a salary of £115 per annum as Medical Officer, and £15 per annum as Sanitary Officer, together with fees for Registration and Vaccination.

Applications for the Office, with Diplomas and Testimonials, will be received by the Assistant Honorary Secretary, "James Sproul, Esq., Skeage, Brookeborough."

Personal attendance of Candidates will be required on the day of Election.—By order,

J. O'K. HALY, Clerk of Union.
25th January, 1876.

ROTUNDA LYING-IN HOSPITAL, DUBLIN.
Master:
LOMBE ATTHILL, M.D.
Assistant-Physicians:
ARTHUR V. MACAN, M.B. RICHARD D. PUREFOY, M.B.

This Hospital (the largest Chartered Clinical School of Midwifery in the British dominions) contains Wards for the treatment of Diseases of Females, in addition to the Wards appropriated to Lying-in cases.

A large Dispensary for the Diseases peculiar to Women is connected with the Hospital.

Clinical Instruction in Midwifery and the Diseases of Women is given daily.

The pupils are privileged to attend the Cow-Pock Institution, Sackville Street and York Street.

The Lectures are recognised by the Royal College of Surgeons in Ireland, London, and Edinburgh; the King and Queen's College of Physicians; the Apothecaries' Hall of Dublin and of London; the Army and Navy Medical Boards; and all other Licensing Bodies.

The Diploma from this Hospital is recognised by the Poor-law Commissioners as a qualification in Midwifery for all Hospitals and Dispensaries under their control in Ireland.

Accommodation is provided for a limited number of Intern Pupils.

Pupils can enter at any time.

Applications to be made to Master or Assistant-Physicians, at the Hospital, Rutland Square.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.
PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office, 40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

ONE MILLION STERLING
Has been paid as
COMPENSATION FOR DEATH AND INJURIES
Caused by
ACCIDENTS OF ALL KINDS,
By the
Railway Passengers' Assurance Company,
HON. A. KINNAIRD, M.P., Chairman.
PAID-UP CAPITAL AND RESERVE FUND, £180,000.
Annual Income, £200,000. Bonus allowed to Insurers of 5 years' standing
Apply to the Clerks at the Railway Stations, the Local Agents, or
64 CORNHILL, and 10 REGENT STREET, LONDON.

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,
Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER VII. (*continued from p. 65.*)

ANATOMY. (*a*)

Anatomy is concerned with the Statics of the Nervous System. The Nervous System is a representing system. A knowledge of the anatomy of any section of it is a knowledge of the parts of the body which that section represents and of the degree of complexity with which it represents those parts. Now the only things it can represent are Impressions and Movements.

The word Impression thus used is obviously an awkward one; I do not know what other word to use. I mean, of course, an alteration effected at the origin of an afferent nerve producing activity in a nervous centre because the nerve fibre is connected with that centre; the principle of action is the same if the impression leads by the intermediation of one or more lower centres to an active state in the very highest centres. I use the word because it implies nothing, at least I intend it to imply nothing, as to sensation in the sense of mental state. It is a name for an active physical state only, Whether the change at the origin of an afferent nerve leads to further physical changes attended by a conscious state (that is, to a sensation) or not depends partly on the height of the centre which the current developed reaches and partly perhaps on the *amount* of disturbance it provokes there. Nerves from all parts of the body (from the tissues generally and viscera, not from the surface only) are included among afferent nerves; and among efferent nerves are included those which pass from the central nervous system to all parts of the body, not those which pass to muscles only. The expression disturbance or excitation at the periphery would perhaps be better than "impression" in the case of the afferent nerves arising in tissues and serving in the systemic sensations, as the word impression seems to imply some outward object acting; but it is convenient to make the one word impression do for all. Then all efferent nerves do not provoke movements, some stop movement, are inhibitory. The inhibition of movements is represented in nervous centres. Again, some efferent nerves pass to the penetralia of glands and provoke secretion. (*a*)

It is plain enough that the lower nervous centres represent impressions and movements. But the very highest nervous centres can only be highly complex sensori-motor arrangements. (*b*) There is nothing else that they can be. The highest centres *re*-represent the impressions and movements already represented in all lower centres, and represent very largely the most special of all bodily impressions and movements, those of the eyes, (*c*) the hands, &c. Thus

(*a*) I should say that all that may appear to be of importance in this chapter is little more than a reflection of certain of Herbert Spencer's psychological teachings, or an application of them to cases of nervous disease, were it not for the fear that I might be guilty of the offence of distorting his doctrines or misapplying them.

(*a*) "—— we shall be considerably helped by thinking of the afferent nerves as *recipio-motor* and the efferent nerves as dirigo-motor; while we think of the nervous centres as composed of libero-motor elements along with elements that perform both the other functions."—Spencer, "Psy.," i., 49.

(*b*) It is supposed that they are not only complex in the sense that they represent innumerable different combinations of impressions and movements, but that they represent the combinations in innumerable different intervals.

(*c*) In former chapters I illustrated the proposition that the unit of composition of the highest parts of the nervous system is sensori-*motor* by the case of the substrata of vision. But in an article, *Med. Times and Gazette*, Aug. 7, 1875, I tried to show that the auditory nerves also have direct association with movement. An hypothesis there stated is that the cochlear division of the auditory nerve is afferent to the heart and arterial system; whilst the tripartite division for the three semi-circular canals is

they represent the whole organism. This is saying that the definition we started the chapter by giving applies to those centres which are in activity whilst we have mental states quite as much as it applies to the lower centres, during energising of which centres there is commonly supposed to be no attendant mental state. (*a*) To find the anatomy of any nervous centre whatever ("mental" or "physical") is to find what parts of the rest of the body are represented in it. Let us take a simple example. Our anatomical knowledge of some particular segment of the frog's spinal cord is derived from such facts as that an irritation within a particular area of its skin developes currents which, being transmitted to that segment, discharge its grey matter; this discharge by connected nerve fibres next developes movements in such and such muscular regions. What are physiologically reflex actions are anatomically sensori-motor arrangements. (*b*) The same is true of the centres which are the substrata of mental states in man. (*c*) Let us return to an old illustration. When we see a brick it is plain that a certain part of the surface (the retina) is impressed, and equally plain that there are associated movements of the ocular muscles; the sensory element is the peripheral part of the mechanism for colour of the object (surface), the motor element for its shape and size (extension). And, of course, as we are conscious of the brick, (*d*) (only a technical way of saying *we* see it) the disturbance of the retinal impression effects ultimately an active change in the highest centres, which provokes impulses carried by motor fibres to the ocular muscles. The arrangement is here as it is in the cord, sensori-motor, but one infinitely more complex and special than our sketch implies it to be. But we can think of the brick when it is removed. Now when we do so we of necessity think of it as in the environment, and therefore the substratum of the visual idea of the brick can only be made up of elements which represent a past experience of seeing it in the environment. All we could learn of the brick when we first did see it—we speak of what occurred physically at the periphery—was from the impression it made on some part of the surface of our bodies (the retina) and from our reacting movements (ocular) upon it. The nervous arrangement concerned in this actual experience and partly developed by it, or, let us say modified (*a*) by it, remains as the physical substratum of all we can ever after know of the brick in its absence. It represents an adjustment betwixt the organism and the environment. After seeing the brick the modification (or, we might say, education) in a certain nervous arrangement is an actual part of our body. But the excitation or discharge of this modified nervous arrangement having ceased with the removal of the brick, the idea becomes latent; the adjustment is potential. For when at any time afterwards the mere central parts of that arrangement are re-excited even but *slightly*, an idea or vision of the brick is roused, although in a faint form; and as there is a more limited (only a central) excitation, the idea is less vividly referred to the environment. (*b*)

What we have been saying is equivalent to repeating that the substrata of consciousness represent impressions and movements. For the highest nervous arrangements are the substrata of consciousness. We have been speaking of a particular state of consciousness arising during either a strong or a slight excitation (corresponding to "vivid" and "faint" ideation) of a limited part of the substrata of consciousness—that part which represented certain retinal impressions and adapted ocular movements. It is understood of course that it is the particular arrangement and the definite association of these nerve fibres and cells answering to impressions and movements which constitute the substrata. We have to discover the nature of these arrangements. For a mere number of recipio-motor, libero-motor, and dirigo-motor elements only form the "empirical" formulæ, not the "rational" formulæ of the substrata of mental states.

Let us state the principle involved in our definition more generally as a sort of recapitulation.

Everybody believes that our ideas are acquired by experience, or rather, that experience is an essential factor. This is admitted by those who hold that we have innate forms of thought, whether they admit the Spencerian doctrine that our forms of thought are inherited experiences of things or believe that they are innate in the old sense of the word. In other words, ideas are acquired during the correspondences betwixt the organism and its environment—the innate forms are then developed and filled up. The sensori-motor arrangements we have been speaking of constitute the inherited mechanism by which these correspondences can be effected; the mechanism itself being perfected during the process. It is only stating this principle most simply (with regard to the highest mental processes at least) to say that ideas are acquired during contact of objects with particular parts of the surface of

---

afferent to centres for movements which are leading in locomotion. The nerve we call auditory might with propriety be called affero-cardiac and affero-locomotor. Associated with these movements the auditory nerve serves in the estimation of Intervals (Time) as the eye does in Extension (Space). I suppose also that systemic sensations have their motor congeners in movements of the skin, intestines, arteries, &c.—that there are systemic sensori-motor processes.

(*a*) I say "as commonly supposed," but it seems to me more and more evident that we must accept Lewes's doctrine—that a "Sensibility" attends energising of all centres. The reader will note, however, that there is nothing in the text to imply that when the nervous centres have reached an exceeding complexity of structure any kind of physical states *becomes* any kind of mental states, but simply that as centres become exceedingly complex a mental state *attends activity of them*—is parallel with their activity. This is the most commonly received doctrine. Mr. Lewes, on the contrary, thinks "that the neural process and the feeling are one and the same process under different aspects."

(*b*) But such facts as that the cord has certain sized and certain shaped columns of white matter and certain shaped areas of grey matter are facts of morphology. So, too, are facts as to the course of fibres and arrangements of cells disclosed by microscopical examination. The latter is not Minute Anatomy, but Minute Morphology; and however minute it becomes it does not turn into physiology. It is only when the shapes of cells and course of fibres, &c., are shown to be subservient to the reception or conduction of particular impressions and to the development of related movements that morphology ceases or rises into anatomy.

(*c*) There is reflex action here, too, but it is imperfect reflex action; reflex action "breaks down" in the very highest centres.

(*d*) It is understood, of course, that no idea can occur singly; it can exist only as one of a class. "To say what a thing is is to say what it is like"—(Spencer). Moreover, a visual idea, as do other ideas, requires translation into a tactual idea before its meaning can be fully known (Spencer). I have suggested that there is evidence of the mechanism for the physical side of the process of translation in certain cases of hemiplegia of extensive range. But for purposes of limited illustration we consider the idea and its physical substratum as occurring singly. Indeed, what we speak of in the text as a "correspondence" is betwixt the organism *as a whole* and some part of the environment.

(*a*) What the exact nature of the structural modification may be we do not know. Huxley ("On the Hypothesis that Animals are Automata," *Fortnightly Review*, Nov., 1874, p. 563) says:—"I do not know that any modern theory of the physical conditions of memory differs essentially from these [Haller and Hartley], which are all children—*mutatis mutandis*—of the Cartesian doctrine. Physiology is at present incompetent to say anything positively about the matter or to go further than the expression of the high probability that every molecular change which gives rise to a state of consciousness leaves a more or less persistent structural modification, through which the same molecular change may be regenerated by other agencies than the cause which first produced it."

(*b*) Or, using popular expressions, we "think of the brick," "are conscious of it," "see the object ideally," &c. That excitation limited to central nervous arrangements will suffice in ideation is proved by such facts as that when the eyeballs are atrophied the patient still dreams of objects he formerly saw. Occasionally the irritation of the stumps of the optic nerves provoke, even during waking hours, not merely "sparks and colours," but definite spectral visions of persons and things. Indeed, the annoyance from this is one reason assigned by Graefe for the operation of section of the optic nerves of atrophied eyeballs.

our bodies, and during the reaction of parts of our bodies on the objects. (*a*)

So far we have illustrated by sensori-motor processes representing surface impressions and corresponding motor reactions of the surface. But we have many times insisted that the units of the substrata of consciousness represent the whole body: they represent the tissues (including the skin *as a tissue*), the viscera, the intestines, heart, arteries, &c.—that is to say, they receive afferent nerves concerned in systemic (Lewes) or organic (*b*) (Bain) sensations, and they send out also fibres for the corresponding organic or systemic movements. That these are represented in the very highest nervous arrangements disease shows. And we should infer such representation *à priori* from the constant accompaniment of intellectual by emotional states. For evidently these systemic sensations and movements are concerned during emotional states. The nerves *from* the skin, viscera, &c., and nerves *to* the heart, arteries, intestines, &c., are only, of course, the raw material of the substrata of emotional states; it is their particular arrangements which constitute the substrata of emotional states. They, too, are sensori-motor, and no doubt in the highest centres sensori-motor arrangements of exceeding great complexity. (*c*)

The systemic sensori-motor arrangements cannot be said in any ordinary use of the expression "to represent adjustments betwixt the organism and its environment." They represent adjustments of parts of the organism to one another. The best examples of these adjustments are those furnished by the innervation of the circulation; these adjustments are very intricate. But since on Spencer's doctrine of nervous evolution all our nervous arrangements are the sum of the residua of ancestral correspondences betwixt the series of organisms and their environments the systemic sensori-motor arrangements would in a sense come under the definition. We shall, however, say that they represent parts of the organism in adjustment to one another.

In saying that the substrata of consciousness represent or re-represent the whole organism, it is not meant that there is a dead uniformity of representation of all parts of the body in these highest nervous centres. Whilst they represent impressions and movements of all orders the most special of the impressions and movements (those of the eyes, head, and hand) will have the leading representation. There will be innumerable degrees of subordination down to representation of the most automatic of all movements and the most organic of all sensations (those of the tissues, muscles, viscera, &c.).

In speaking so far of the substrata of consciousness we have ignored the fact that they are in several parts of the cerebrum. We spoke of the substrata of consciousness as being the highest nervous arrangements. Yet to avoid misinterpretation we pointed out explicitly some time back that we do not really suppose there to be one fixed seat of consciousness. Now, if the expression may be permitted, we shall speak of several highest nervous arrangements.

Consciousness is not an unvarying independent entity. Consciousness arises during activity of *some* of those of our highest nervous arrangements by which the correspondence of the organism with its environment is being effected. Our present consciousness is our now mental state; it is such or such according to the kind of correspondence now being effected. As this correspondence is continually changing, the nervous arrangements concerned are continually different. Our present consciousness is, psychologically speaking, the present relation betwixt the subject and the object, or, anatomico-physiologically speaking, it arises during the present adjustment of the organism to its environment. It is an anatomical problem to discover where in the nervous system those nervous arrangements lie which are in leading activity, whilst we are conscious thus or thus. The steps are—(1) What is the adjustment, and what parts of the surface or periphery are concerned in it? In visual ideation the adjustment is retino-ocular, the retina and ocular muscles being the parts of the periphery concerned in it. The further question is—(2) Where are the highest nervous centres representing those parts of the body? I do not ask the reader to take the answers I am about to give as facts, but as *admittedly imperfect* hypotheses. When we think of the brick as coloured, the *leading* activity is of nervous arrangements in the right posterior lobe. This is intended to mean that it is of a part where retinal impressions are most represented in complex combinations and definite associations. When we think chiefly of extension (the shape and size) of the brick, the *leading* activity will be in the left anterior lobe—that is, in a part where certain ocular movements have the leading representation. What is quite certain is that, as from moment to moment we are differently conscious—that is, are conscious of different kinds of things, the nervous substrata in activity cannot be the very same at each moment. There is as certainly a localisation in some part of the nervous system of arrangements concerned in each particular state of consciousness as there is a localisation of movements of the hand, or of the face, or of the foot. I do not mean, of course, that we have yet been able to localise in the former as we have in the latter, nor that the localisation is equally definite in the two. When we think of one object, as a rose, the substrata excited will not be just the same as those excited when we think of another object, as a brick.

The excitations above spoken of are healthy nervous discharges. Metaphorically speaking, they cause development of the rational formulæ of the nervous system, and correspondingly of clear and definite mental states; and as the excitations occur at certain intervals they are in orderly sequence. But from the excessive and sudden discharge of these substrata in an epileptic fit there only occurs the crudest mental states (clouds of colour), and not movements of the eyes (nascent or actual), but spasm of the ocular muscles; there is a *sudden excessive* development of innumerable nervous arrangements all at once. The spasm and crude sensations (or rather the implied excessive excitations of sensory nervous centres), as it were present us with crude heaps of the raw material of these substrata, not even in the rough order of their empirical formulæ.

(*To be continued.*)

(*a*) Of course the word "contact" is used here in an unusually extended sense, not for tactual impressions only, but for aural and retinal.

(*b*) The systemic sensations are numerous. Those from the tissues might be called "common systemic sensations;" those from the viscera, "special systemic sensations"; whilst hunger and thirst deserve the name of "compound systemic sensations."

(*c*) "[Emotions] are of far more involved natures than sensations, and imply the co-operation of extremely intricate nervous structures."—Spencer, "Psychol.," vol. i., p. 122.

A NEW METHOD OF PREVENTING THE SECRETION OF MILK IN THE FEMALE BREAST.

By John Wm. Lane, M.D., L.R.C.S., &c.

I have for more than ten years employed the following method to prevent the secretion of milk in the breasts of women who may have had still-born children, or who, after having nursed their child for a few months, found it necessary to wean it. It is perfectly clean and painless as far as my experience goes, and as such I beg to recommend it to the notice of my medical brethren.

We will take for instance the case where the infant has been born at the full period, but is dead, or dies within a few hours of its birth. The milk makes its appearance in the breasts generally about the second day, sometimes longer, and sometimes it is ready when the child is born, and in the case of still-born children my experience leads me to think that in such cases it makes its appearance earlier than when the child is born alive. My plan consists in taking a piece of emplastrum adhæsivum of about ten inches square, round the corners, cut a hole in the centre for the nipple, then from the centre of each corner make

a straight cut towards and within two inches of the centre hole ; having now got it ready, let the patient lie on her back, her body being perfectly horizontal ; warm the plaster and place it over the breast, then strap one of the lower corners down first, draw the opposite one tightly upwards and fix it in its place, then the other lower corner, and lastly the opposite upper one, having drawn it sufficiently tight first ; now take a piece of plaster two inches wide and about sixteen or eighteen inches long and put it on from below and outside the breast, across close by inside of nipple, and fasten the end over the clavicle ; another piece may also be put on in an opposite direction, it being drawn over the shoulder. Of course, in cutting the plaster and strips the size of the breasts must be taken into consideration, there being so much difference in the size of female breasts.

The above plan I always follow when one of my patients wish to dry the milk, as they usually call it, or where they are compelled to do so either from the death of the child or any other cause. I also am certain strapping will prevent mammary abscess if resorted to in the earlier stage ; I at least have found it do so in many cases.

A CASE OF CIRRHOSIS OF THE LIVER. (a)

By S. M. MacSwiney, M.D , M.R.I.A.,
Physician to Jervis Street Hospital.

M. L——, æt. 40, entered Jervis Street Hospital August 7th, 1875.

History.—She was a married woman and had two children. Her habits had been for some years decidedly intemperate : she had frequently drank two, and even three, glasses of whisky in the day. Her health had been fairly good until about six months ago, when she began to feel weak each day. Her appetite failed her, and she experienced occasionally pain in her right side, as well as in the region of her stomach. Nevertheless, she continued to follow her customary avocations, and had worked as usual as a charwoman during the day of August 7th, although feeling very unwell. On coming home that night she took a dose of Epsom salts—a popular remedy for almost all ailments. In about an hour afterwards vomiting came on, and she brought up a large quantity of blood. She vomited repeatedly within the next couple of hours, bringing up blood each time ; finally, she was taken at midnight to hospital in a state of great exhaustion, and seemingly dying.

State on admission.—She was pale and cold, and in a condition of almost extreme collapse from loss of blood when received into hospital. Suitable restoratives were applied by Mr. Hughes, the medical "resident," and she rallied after some hours. Medical examination, made next day, elicited the following facts : Her face wore a slightly jaundiced, somewhat dusky, and very anæmic expression. There was tenderness upon pressure over the stomach. The normal extent of hepatic dulness was diminished, that of the spleen, on the other hand, was increased. She had no ascites, no anasarca, no œdema. The urine she passed was small in quality, high in colour and specific gravity, and did not contain either albumen or blood discs. She died on October the 4th.

During the eight weeks that she was under treatment in hospital her symptoms presented the following points of interest : She had great and almost constant irritability of stomach ; her thirst for cold drinks was extreme, and she vomited a considerable part of whatever she made use of. Her appetite for food was quite gone. She suffered from severe pain, referred to her right side, and she could not sleep by reason of this pain, except by the aid of morphia hypodermically administered. She daily became worse, and manifested new symptoms of serious import. Her feet commenced to swell and "pit" upon pressure. It is noteworthy that the first symptom of dropsy which presented itself in this case was shown in the œdema of the lower extremities. To this succeeded, after some time, a rapid enlargement of the abdomen, and soon a very considerable ascites was established. The distress caused by the great accumulation of fluid was so extreme that paracentesis abdominis had to be had recourse to twice at an interval of a fortnight, and with the effect of giving very great relief to all the troublesome symptoms. After the second "tapping" the wound made by the trocar did not heal, but a fistulous opening remained, and through it, from time to time, the fluid in the peritoneum drained out. Owing to this circumstance no further accumulation of fluid took place ; she was, in fact, in a certain sense, cured of the dropsy. She rallied wonderfully in every respect, after this second "tapping," all her more distressing symptoms disappeared, the vomiting ceased, she ate and slept well; she even put up some flesh, and regained a slight colour in her face, which had up to this time been sallow, dusky, and noticeably, but not deeply, jaundiced.

On the 4th of October, however, she suddenly started up in bed, vomited a large amount of blood, and was instantly dead.

I now exhibit to members of the Society the following organs removed at the necropsy—viz. :

1. The liver is much contracted, hard, extensively nodulated, brownish-yellow in colour ; on section it presents a granular appearance, yellowish in some parts, dark brown in others, whilst fine white lines run irregularly over the surface of the section. A microscopic examination showed the presence of much fibrous tissue, and numerous cells in every stage of atrophy or degeneration.

2. The spleen is very considerably enlarged ; when removed it seemed laden with much dark blood. In no other respect does it present any appearance calling for special notice.

3. The kidneys are indissolubly united, constituting what appears to be but one organ, which is of crescentic shape. There are, however, these two ureters, which are normal in every particular. This specimen, then, is a good example of the blending of the two renal organs into one glandular body.

4. The stomach contained much blood, mixed with some mucus at the time of removal, but it presents nothing abnormal so far as I can judge in its structure. Careful examination has failed to detect any evidence of rupture of blood-vessels ; there were no extravasation patches recognisable at the time of its removal from the body ; but the mucous membrane was deeply and generally stained from imbibition of blood.

The disease from the effects of which this patient died is one which frequently comes under the notice of the physician, and but too often overtaxes his skill to remove ; as there is far from being complete agreement amongst medical men upon many points in the etiology, symptoms, and treatment of cirrhosis of the liver, I beg leave to briefly recapitulate with a view to the promotion of discussion, some of its characteristics in these respects, which are already well known to members of this learned Society.

Dr. MacSwiney then passed in review the most important questions connected with the disease, and discussed at considerable length its etiology and pathology. Finally, he observed, "There are, I venture to say, few diseases to be met with which present such a number of unsolved or disputed questions on points of importance as cirrhosis of the liver. Thus, at present, the following inquiries relating to various features of the disease still remain to be answered :—

1. Which is it, an inflammatory exudation or a degenerative process which precedes the atrophy of the liver in cirrhosis ?

2. Is cirrhosis ever due to any other cause but drinking undiluted spirit ? And if it be sometimes due to other causes, which is the generally received doctrine, then,

3. What are the other causes of true adhesive hepatitis ?

4. Is the disease caused by spirit-drinking different to

(a) Abstract of a paper read before the Medical Society of Dublin, January 12th.

the other forms, not only in cause, but also in its anatomical characters?

5. Are the different so-called varieties of cirrhosis which are often undistinguishable by their symptoms during life anatomically distinct?

6. On what does the swelling of the spleen in the disease depend?

7. Can the disease be cured in the early stage?

8. What is the nature of those cases where the symptoms are absent during life, and the disease is for the first time recognised at an autopsy?

It is to be hoped that ardent investigators in the department of medicine will ere long clear up whatever is difficult or obscure in the etiology and pathology of cirrhosis of the liver; meantime, I shall now only further observe that the following constitute, in my opinion, the chief points of interest in the case which I have had the honour to bring before the Society to-night—viz.:

a. The suddenness of the invasion of the symptoms.

b. The severe gastro-enteritis from which the patient suffered the greater part of the time.

c. The fact that the œdema of the lower extremities distinctly preceded the occurrence of the ascites.

d. The treatment by "tapping," which was followed by

e. The fistulous opening in the abdomen.

f. The sudden death after profuse hæmatemesis.

ON THE CAUSES OF EPIDEMICS.

By T. Baker, LL.B.

(*Continued from p.* 90.)

True, such contagion-fears have influenced the populace, and led to neglect of the sick through quarantine laws, and various other ways; but is such a humane or manly feeling? Should not medical men seek for every means of averting the evils it engenders? Does not the kingdom blush when a poor woman suffering from cold and privation, and pronounced to be "feverish," is turned out of her lodging forthwith for fear of contagion, and being refused admission at two other places, dies on the stones? Yet this happened in London last year! reminding us of the Spanish sailor with yellow fever dragged for three hours at night by a rope round his neck to an uninhabited lazaretto, and there left without water or attendance to die!

How many have been sacrificed to this fear? And what have we arrived at now? When, in the present day, it is proposed to erect a fever hospital, the populace or the property holders rise almost in arms against it. The sick are not to be treated, forsooth, lest "contagium" should fly out of the windows!

Perhaps we cannot wonder, when so many stories have been published to prove that disease of various kinds has been imported by ships. Yet, if we would look into the matter, could any port exist without the perpetual arrival of ships? Could, according to this hypothesis, any local miasm ever engender disease? The unacclimated always suffer first from want of seasoning. Are not the crews of ships precisely in that condition? Plenty of local predisposing causes exist within the ship, probably, to make the crew more liable to be affected by the superadded poison as soon as the shore breeze shall waft it towards their vessel. Will these not be naturally first struck by disease in an about-to-be-epidemic-stricken port?

But why the port before the inland town?

Do we not know that the mud banks of rivers—the marsh land,—and, above all, the mixture of tidal salt water with the foul fresh, are among the worst sources of febrile miasma? Hence importation by ships will always be a readily improvised cause of disease; yet may it not be in almost every instance a complete fallacy?

The newest importation story is the introduction, "it is believed" (this is quite sufficient evidence), by H.M. ship *Dido*, of measles into the Fiji Islands. The islanders may possibly have been most cleanly in their habits; it may be readily "believed" that the ship did the mischief, like all the other ships before alluded to. And it seems evident that the rushing into water holes by the sick, the neglect of the dead so that the pigs mangle the bodies, and the noisome effluvium therefrom, have as yet taken very little of the blame for the unwonted mortality from the unlucky *Dido*. But may not this state of things suggest the probability that missionary reports of whole tribes having formerly been swept away by small-pox rested on possibly questionable grounds, at least as regards the virulence of that eruption had it been left to nature or sensibly treated?

So also the low-lying and dirty parts of a city or heavily-manured rural district may, in a moist open calm season, emit foul vapours, which, not concentrated enough to strike the acclimatised inhabitants of that district, might nevertheless be just wafted by a gentle breeze against some neighbouring hill side, the dwellers on which, themselves provided with sanitary appliances, and therefore unused to the poison (but plenty of other evils co-operating doubtless), shall suffer an epidemic, and wonder whence it came, groping after some fanciful contagion story; and if the first person attacked can only be said to have been within any known distance of another patient having a similar illness, or even to have received a letter from such an one, the world is satisfied, and the real cause is overlooked. It is suspected that this was the case at Norwich a year or two since.

With reference to the general effect of any particular epidemic influence, may it not be commonly felt, without in numberless instances producing the specific epidemic attack? At Baltimore, in 1850, all the inhabitants felt uncomfortable and "out of sorts," yet no cholera occurred, because the town had been thoroughly cleansed as a forewarned precaution, except in one spot, which had been overlooked—a filthy marsh close to the workhouse. Here cholera broke out, on that side the house only. The cause was found and removed, and the cholera stopped.

Thus also, in 1849, the writer of this paper, then attached to the General Board of Health, working with and among cholera visiting people, sitting up sometimes three nights a week over cholera statistics, &c., distinctly felt the epidemic influence throughout the season, in uncomfortable sensations, but had no fear of contagion and suffered no attack. When, in 1853, he visited every house in Croydon where a death from the famous fever of that year had occurred, the epidemic had passed off. He saw one case only, a poor girl moaning in a room with a window that would not open, and vainly remonstrated with the mother; but the marsh miasm which appeared to have producad that outbreak had then been dispersed by genial sunshine. At the request of a philanthropic peer he visited Tyndall's Buildings, Gray's Inn Lane (now swept away), to take a night census of the population there crowded together. A great variety of surroundings existed even there. A general average of disease-generating dirt (as well as of character requiring the guard of a detective).

Why, however, is it that epidemics prevail at one time, and not at another? And why in varying form? Has sufficient attention been directed to differences of season; dry cold winds producing lung and throat disease tendency; hot and moist or mild and wet seasons inducing exanthemata in forms varying in accordance with accompanying circumstances? May not these circumstances of season be far more closely investigated? Has, for instance, small-pox any favouring conditions brought about by excessive moisture? 1871 was wet in the south and about London; in 1872 the rainfall was above the average in the north: was it so in Scotland and Ireland? and was it so concurrently with the small-pox epidemic in those countries? There was no small-pox in 1871 at Tewkesbury, yet the average of 10 years previous shows that disease to be generally far more prevalent in that district than in the surrounding districts. Does this

arise from the flooding produced by the confluence of the rivers there?

If so, was 1870-1 drier than usual?

If it should turn out that difference of season developes from local causes different tendencies, so that the disease, ever ready in unhealthy (improperly stimulated, under- or over-nourished) bodies to take shape from the added conditions of the season, greatly influenced it may be also by the prevalence or absence of wind and storm, then we should have surely almost enough to explain any epidemic. Still it is commonly believed that there is yet something else requisite beyond the physiological state of the persons attacked, and beyond the development of local causes, modified by season, to account for most epidemics.

It may then be well to ask whether such superadded cause might not be engendered at sea, during calms, under a tropical sun, or by volcanic action, destroying marine life? Foul vapours conveyed by subsequent breezes, divided by ocean currents and gulf streams, aided by mountain draughts, and blown hither and thither chiefly along the course of rivers to aid in developing the almost-ever-sufficiently-present-previously-existing causes towards an epidemic outbreak? When ocean calms are long continued, the water appears to lose its vitality, and to become a mass of decomposing material. Strange-looking jelly-like masses and animal monsters are formed without limit. Sir Richard Hawkins, in his account of calms, in 1593, as the cause of sickness, writes:—"Were it not for the moving of the sea by the force of winds, tides, and currents, it would corrupt all the world. The experience I saw in 1590, lying with a fleet of H.M. ships about the islands of the Azores almost six months, the greatest part of the time we were becalmed; with which all the sea become so replenished with several sorts of jellies, assuming the form of serpents, adders, and snakes, as seemed wonderful: some green, some black, some yellow, some white, some of divers colours, and many of them had life, and some there were a yard and a half, and two yards long; which had I not seen, I could hardly have believed: hardly a man could draw a bucket of water clear of some corruption."

Or, as Coleridge has it—

"The very deep did rot."

Should intelligent investigation lead to the discovery that we may look in this direction for one of the originating causes of special epidemics, it may be for science, if possible, to invent some method of protection for a country like India, for instance, from such noxious air-blasts as may probably be prognosticated by meteorologists, and forewarned by telegraph, in the same way that the hoisting of the drum now warns the mariner to seek safety within harbour from impending storm.

If ever such a time arrive, well shall we be able to afford to place all fears of mere contagion from person to person among the exploded superstitions of a bygone age!

Clinical Records.

CASE OF NECROSIS OF THE UPPER JAW.

By C. P. Coombs, M.D. Lond.

The following short notes relate to an unusual form of disease. The patient was employed at an artificial manure-yard, in which there is a tank for the maceration of the carcases of animals who have died of disease or accident. When thoroughly decomposed, the semi-fluid contents of the tank and the crushed bones are mixed with sulphuric acid, and then submitted to further processes. As mixing the animal matter with the acid formed part of the patient's work, it is fair to conclude that he was often exposed to the fumes of phosphoric acid, though the other men employed in the yard speak of the odour as being more like that of decaying matter than like that of lucifer matches.

J. T——, æt. 45, a short man, with a pale unhealthy face, complained for some weeks of occasional face-ache, and on November 13, 1875, came to my house to show a swelling in the roof of the mouth. An oval tumour, about an inch from before backwards, and three-quarters from side to side, occupied the left half of the hard palate. It was tense, and of purplish colour. Two days later the swelling had gone away, a grey slough had taken its place, and the cheek and eyelids were red and swollen.

By November 17 three of the molar teeth had fallen out, the slough had gradually extended its area, and the alveolar process of the jaw (where the teeth had come out) was exposed.

From this time the eyelids swelled more and more, and the cheek became purple at a spot about an inch below the left eye, where the skin gave way, and much venous blood escaped.

The patient's condition was at this time (second week) very bad; the fœter of his breath and the discharges filled the house, in spite of carbolic acid and chlorine. The sloughed state of the palate interfered with his taking much nourishment, and his appearance was very bad, the chemosed conjunctiva protruding between swollen lids, dark blood oozing from the opening in the cheek. During the third week he became very drowsy, was always asleep, or only semi-conscious when I visited him. The slough in the palate became loose, and pieces came away, the slough apparently including the periosteum and part of the horizontal (palatine) plate of the superior maxilla. With occasional hæmorrhage, and less power of taking food, the unconsciousness became more complete until the patient's death, on December 7th.

Remarks.—I have never met with accounts of necrosis of the jaw from combined phosphorus being inhaled, nor is it usual to speak of injury to the upper jaw from the fumes. The patient was not at all intelligent, nor did he take any great interest in his illness or its causes. At first it appeared as though something akin to malignant pustule had been produced by some insect conveying poisonous matter to the patient's mouth or nose from one of the diseased cattle brought to the manure-yard.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Friday, January 28th, 1876.

Christopher Heath, F.R.C.S., Vice-President, in the Chair; and subsequently E. Headlam Greenhow, Treasurer of the Society.

NEW OPERATION FOR CATARACT.

Dr. Charles Bell, Taylor of Nottingham, introduced patients who had undergone double extraction for cataract, by a method which he had adopted in favourable cases since 1865. The lens, he said, was removed through a small flap, the base of which occupied a position about midway between the horizontal diameter of the cornea and the corneo-sclerotic junction. The wound healed readily. There was no subsequent astigmatism; and, as there was no trace of the operation a few weeks after its performance, the lower section, on account of its greater convenience, was selected. The patients introduced, who were stated to be average examples of successful cases treated in this way, had central and movable pupils; and all trace of the operation was so completely effaced that it was impossible to say whether the flap had been made upwards or downwards, or that the patient had undergone any operation. Dr. Taylor stated that the highest amount of usual acuity obtainable after extraction was secured in this way, some of the patients declaring that they saw as well as ever in their lives before.

Mr. Macnamara referred to the advisability of not remov-

ing any portion of the iris, and considered such an operation unnecessary if the pupil dilated under the influence of atropine. He believed that to obtain perfect vision the capsule ought to be removed with the lens.

Mr. SPENCER WATSON agreed with Mr. Macnamara as to iridectomy, but as to removing the capsule of the lens, he thought it fraught with great danger, in consequence of the escape of the vitreous, which must almost of necessity take place.

Mr. BRUDENELL CARTER spoke in favour of iridectomy, and considered that the best results could be obtained with that operation.

NEW OPERATION FOR SYMBLEPHARON.

Dr. C. BELL TAYLOR also introduced a patient who had been under his care, in whom was exemplified a new method of treating cases of symblepharon. After the separation of the adherent lid from the eyeball, a thin piece of skin was dissected from the lid, passed through an incision in the tarsal cartilage, and its raw surface brought into contact with the denuded portion either of the lid or the eyeball itself. In this way the two raw surfaces of the lid and eyeball were prevented from coming in contact until the wound had healed, and the eyeball itself was set free. The transplanted skin was nourished through its base in the first instance, which was denuded as soon as it had taken root in its new situation. It then gradually dwindled, taking the place and assuming the functions of the lost mucous membrane.

CASE OF GUNSHOT WOUND OF THE ARM, DIVIDING THE BRACHIAL ARTERY AND MEDIAN NERVE.

Mr. CHRISTOPHER HEATH exhibited the patient, æt. 19, whose history was as follows. He was dragging a gun through a hedge, when the charge passed through his right upper arm from the inner side to the back, without breaking the bone, making two large apertures with inverted and everted edges. When he was brought to the hospital, four hours after the accident, there was no hæmorrhage, and no pulsation below the seat of injury. The hand was cold and numbed, but he could at this time flex the wrist and partially the finger; he could also extend the wrist, thumb, and forefinger, but not the others. The wound was syringed out with carbolic lotion, and dressed with an oakum pad, and the patient made a good recovery. At the present time, all the parts supplied by the median nerve were paralysed, but he had regained sensation by the parts supplied by the ulnar. Flexion of the hands and fingers was now, however, entirely wanting. Extension remained as at first, *i.e.*, he could extend the wrist, thumb, and forefinger, but not the other fingers. The flexors did not respond to faradism, but contracted to a slowly interrupted galvanic current.

Dr. ALTHAUS referred to a case in which the median nerve had been injured, in which recovery of sensation had taken place except in the thumb and index finger; and Dr. Greenhow advised faradisation in such cases.

EMBOLISM OF RIGHT POSTERIOR CEREBRAL ARTERY, WITH YELLOW SOFTENING OF THE OCCIPITAL LOBE, PRODUCING TEMPORARY BLINDNESS; LEFT HEMIPLEGIA, UNCONTROLLABLE MOVEMENT OF THE RIGHT LIMBS, AND ROLLING TENDENCY; DOUBLE OPTIC NEURITIS; DEATH FROM ULCERATIVE ENDOCARDITIS.

Dr. BROADBENT read particulars of this case. The patient, a young man æt. 19, had suffered three years previously from acute rheumatism. Ten days before his admission he suddenly became blind, and had great pain in the head. Five days later, vision having returned, he lost the use of his left limbs, while the right arm and leg were continually in motion; and, unless restrained, he rolled over and over towards the left, falling out of bed and bruising himself severely. The left hemiplegia and uncontrollable movements of the right limbs continued when he was admitted; the hemiplegia not being absolute, but accompanied by slight rigidity and very considerable impairment of sensation. The patient took no notice of persons or objects, but answered questions, and put out the tongue on being urged. His pulse was variable, 120 to 160 or more. Temperature in the right axilla, 99·2°; in the left, 100·6°. A loud mitral systolic murmur was present. The bowels were confined, and, when opened, the fæces and urine were passed in bed. A dose of three grains of calomel was given, and two grains of carbonate of ammonia with two drachms of infusion of digitaliis every two hours. Chloral also was given at night. He was ordered a diet of milk and beef-tea, with four ounces of brandy. There was gradual improvement; and, three days after his admission, an ophthalmoscopic observation, previously attempted in vain, was obtained, and the discs were found to present the appearances of marked ischæmia. Pulse now 108, soft, short, and strikingly dicrotous. A day later, the pulse was 88 and more full. The temperature was still nearly a degree higher in the left (100) than in the right (99.2) axilla. Slight paralysis of the left external rectus of the eye was observed. At the end of a fortnight's stay in hospital, the right limbs were quiet, and there was considerable return of power and sensation in the left side. His speech was rather slow, but there was no obvious impairment of the intellect. Notwithstanding this, however, he not only passed his fæces in bed, but threw them about and bedaubed himself and the bedclothes without any regard to decency. The optic ischæmia was marked, but vision was good. The temperature of the right axilla was 99·3; of the left, 100. At the end of three weeks he passed his excretions naturally. After five weeks he was up and about, eating well, but pale, and still complaining a little of headache. Impairment of power and of sensation in the left limbs was still perceptible. The optic neuritis was subsiding. Distant vision was good, but small print was not easily read. A systolic mitral murmur was heard. The temperature was still never below 99°; usually 100°; it was now equal on the two sides. But for this elevation of temperature, the patient would have been allowed to leave the hospital. Soon afterwards, however, there were symptoms of splenic embolism, and later of ulcerative endocarditis; and he died from this, four months after admission. On post-mortem examination, with ulcerative endocartitis and numerous recent embolisms, there was found softening of the occipital lobe of the right hemisphere from the posterior cornu of the ventricle downwards, and the branch of the postcerebral artery entering the calcarine fissure was occluded and lost in adhesions. It was considered probable by Dr. Broadbent that originally the posterior cerebral artery itself had been blocked up, and not only this branch. The interesting points in this case, on which comments were made, were the temporary blindness, the agitation of the right limbs and rolling tendency, the unusual association of loss of sensation and of double optic ischæmia with embolism of a cerebral artery, and the remarkable indifference to decency persisting when the intellect was apparently good.

Dr. HUGHLINGS JACKSON spoke of the case as one of great importance. He had never seen a case of embolism of the posterior cerebral artery, nor had he seen optic neuritis associated with cerebral softening which had been caused by embolism. It was his opinion that depression of spirits, dread and remorse were connected with the posterior lobes of the brain, and asked whether such emotions had been present in the case.

Dr. BUZZARD narrated a case in which a gentleman continually rolled to the left, and after death a cyst was found in the posterior lobe of the right hemisphere.

Dr. BROADBENT replied that in his case there were no feelings of remorse, and that he himself had noticed the remarkable tendency in some cases to roll on one side when walking.

Literature.

CYCLOPÆDIA OF THE PRACTICE OF MEDICINE. (a)

VOL. X.—DISEASES OF THE FEMALE SEXUAL ORGANS.

THE issue of Von Ziemssen's great Clycopædia, an ambitious undertaking, and the joint work of several authors, has begun. The work is being published in the English, German, Dutch, Italian, and Russian languages. German is the original language of the work, and many of the subscribers are aware that the volumes of the German edition are not being issued in regular succession—some of those treating upon subjects of greatest interest having the precedence, although numbered to conform to the plan of the entire work. This explanation will account for the publication now of the volume which forms the basis of

(a) "Cyclopædia of the Practice of Medicine." By Von Ziemssen. London: Sampson Low and Co. 1875.

the present notice, that by Professor Schroeder, of Erlangen, on Diseases of the Female Sexual Organs, which is the tenth of the Cyclopædia.

The publishers state that the original plan of publication will be adhered to—viz., "*this work will be obtainable only by subscription for the entire set of volumes.* No single volume or series of volumes will in any case be sold."

This, we cannot help thinking, speaking from the purchaser's point of view, is a mistake. It is, however, distinctly stated that the foregoing are the conditions on which the work can be obtained, and those who desire to have this doubtless very valuable set of volumes must, to use Mr. Ayrton's now famous phrase, "order themselves accordingly."

Professor Schroeder is well known, both here as well as in Germany, as an author of repute. His able work on Midwifery has been translated into English by Dr. C. H. Carter, and in this guise has become known to English readers, by whom it has been accepted as an able exposition of this department of medicine.

Great expectations have therefore been excited by the announcement that Dr. Schroeder is the author to whom the gynækological department of the present work has been entrusted. We have now to inquire how he has acquitted himself of the distinguished task allotted to him, and incidentally to notice the quality of the translation into English.

Respecting this latter point, we may at once say that the work has in the main been well done, the rendering being faithful, and on the whole, the English good, though here and there the English reader will detect modes of expression which betray rather a New than an Old World origin. The translation is, in fact, entirely done by our American cousins; and we take pleasure in expressing our belief that they are a very competent band of gentlemen, some of them being, to our personal knowledge, perfect masters alike of German and of English.

We propose to give a critical analysis of the work, as full as the limited space at our command will allow.

The first part is devoted to a consideration of Gynækological Examination and Diseases of the Uterus, and is charmingly translated by Dr. Paul Munde. A brief but clear account is given of the history of the subject, and of the instruments to be employed. As might be expected, Prof. Schroeder prefers the dorsal, or continental position, to the lateral, or English. We do not think he makes good the claim of this as the position *par excellence*, and he is certainly in error in saying that it is the only one in which conjoined manipulation is admissible.

The author goes on to say, however, that "the gynækologist should provide himself with a table or a chair especially devised for the purpose," an admission which will, we think, be sufficient to condemn it in the eyes of English physicians, who certainly manage to conduct their examinations with unquestionable efficiency, and we think with considerably more regard for the feelings of their patients than their German *confrères* are accustomed to display. Another damaging admission made by the author is that the chair he recommends "is not convenient for abdominal auscultation."

The author very properly insists on the great value of bimanual examination, or as he calls it, "conjoined examination."

Respecting the uterine sound, he sarcastically, though by no means unnecessarily, remarks that in using it, "it should never be forgotten that the fingers are holding an exploring instrument which is to seek an already existing canal, and not to bore a new one."

A caution, though by no means emphatic enough, we think, is very properly given regarding the use of sponge and other tents.

The section on Diseases of the Uterus opens with an excellent account of malformations of the genital apparatus. In this connection we may specially call attention to the lucid and accurate description of the condition generally spoken of as retention of the menses or hæmatometra. This, as Schroeder points out, is more frequently due to retention of the menses in the vagina, and not in the uterus, and should therefore be called hæmato-kolpos.

The remarks on Stenosis of the Uterus are good, with the exception of those on treatment. Here the author recommends incision, and surprises us by stating that "inflammation of the uterus and cellular tissue does not ensue if the operation has been performed with clean instruments." This we certainly regard as an error, and, while not ignoring the damaging influence of neglect of cleanliness, would call attention to the evil influence of vitiated constitutional conditions.

The remarks on Hypertrophy of the Uterus are generally much to be commended; but, like most Continental therapeutical teaching, they fail utterly as regards treatment. Our German friends, especially, appear to think they have done enough when they have investigated the etiology and pathology of a given case of disease, ignoring the fact that what patients come to them for, and what they most need, is relief, if not cure. We venture to say that American and English physicians would never rest satisfied with the small modicum of remedial treatment which appears to satisfy some German physicians.

The section on Hypertrophy of the Cervix is singularly well done, the true pathological condition being accurately indicated.

The account of Metritis, Acute and Chronic, is satisfactory, especially of the latter variety, which is sensibly handled. Here we are glad to be able to commend the remedial measures advised, of which local depletion by means of scarifications appears to be the chief.

Acute and Chronic Endometritis are next considered, and a very sensible caution is given against active attempts at cure in the acute stage in the following terms: "Usually there is no need of any special treatment. Indeed, we must emphatically advise against the use of different local applications in acute endometritis."

The true pathology of "mucous polypi" is succinctly stated in connection with the subject of cervical endometritis; and this is followed by a description of the closely allied condition, "Follicular Hypertrophy of the Lips of the Os Uteri."

The account of Erosions and Ulcers of the Vaginal Portion of the Uterus is but meagre. It is, however, fairly done so far as it goes, and we may heartily commend the author's remarks on the injury likely to be caused by the evil, and we fear but too prevailing, practice of applying nitrate of silver to the cervix uteri.

The section on "Displacements of the Uterus" is good, generally speaking, especially as regards etiology and pathology.

As regards treatment, we are told that the intra-uterine pessary is the best method of treating flexions, but the author is forced to admit that it is dangerous, and that "it is quite necessary to select proper cases for the treatment;" these are "pure flexions uncomplicated by inflammatory processes." Prof. Schroeder very properly enjoins the removal of the instrument at the catamenial periods.

The section on Descent and Prolapse of the Uterus is very ably done. We are not acquainted with a better or more reliable guide to the subject than is here given. Such troubles are of exceeding frequency in this country, and often sorely tax the patience and ingenuity of the medical attendant. Where a well-adapted pessary fails to afford the desired relief, some operative procedure may be resorted to, such as elytrorraphy, episiorraphy, or a combination of the two, elytro-episiorraphy.

A fair account is given of Inversion of the Uterus; and a little is said about that rare condition, Hernia of the Uterus.

Then follows a full and excellent account of Fibroids of the Uterus. The pathological account of these growths is of a high order, the true characters of the different forms being clearly pointed out. The rise, progress, and decline of these tumours, and the possible complications which may arise in the course of their existence, are all admirably portrayed.

The section on Malignant Growths is also well done, and here again acquaintance with pathological knowledge is largely displayed.

Professor Schroeder speaks very highly of the treatment of Cancer of the Uterus by means of bromine, for the introduction of which he rightly gives the English credit.

A fair account is given of the Physiology of Menstruation. The new views propounded by Kundrat and Engelmann are considered, and the author declares his leaning towards them. The account of amenorrhœa is very poor; and nothing better can be said of that of menorrhagia. Dysmenorrhœa again is but feebly dealt with, except as regards the membranous form, which is, by comparison, over fully considered. No new light is, however, thrown upon the subject.

In marked contrast to this is the full and generally speaking excellent account given of diseases of the Ovaries and Fallopian tubes. The author gives evidence of extended acquaintance with the subject, and has laid under contribution all the latest and best works on the various points discussed. He makes one unfortunate error, however, in respect of the clamp supposed to be used by Mr. Spencer Wells for securing the pedicle in ovariotomy, for he figures as Mr. Wells's "new clamp" one which he has long since discarded. This is singular, since Professor Schroeder shows considerable familiarity with Spencer Wells's operative procedures.

Peri-metritis and para-metritis are considered after the fashion that they usually are; and a most unsatisfactory fashion it is. There is the usual futile attempt to explain the phenomena supposed to pertain especially to each, but which cross each other constantly; the result being confusion and helpless ambiguity. These remarks apply with equal force to the subject of pelvic hæmatocele, where again the same confusion reigns. Still the author is only reproducing the ordinary ideas of the day.

Malformations and Diseases of the Vagina are much more satisfactorily dealt with, and we may justly speak in praise of the way in which the subject of Uro-genital Fistulæ is handled. In reference to the production of such fistulæ, the author very justly says that it is not the use of instruments, but the delay in resorting to them, which is so fertile a cause of the accident. "In fact," he says, "it may even be said that the majority of fistulæ are owing to the neglect or too late performance of an operation."

The section on Diseases of the Vulva opens with a full account of the malformations of the parts, in which the deviations from the normal course of development are clearly indicated. This is followed by a description of the inflammations, neoplasms, &c., which is instructive.

Rupture of the Perineum is then dealt with, Simon's operation of perineoplasty being recommended as affording good results.

Pruritus of the vulva is briefly, but on the whole, well considered. The author praises carbolic acid as a remedy. He confesses, however, that it is, with him, but a new found remedy, and states that he has only used it in six cases. It answered very well in these. The volume concludes with a meagre account of coccygodynia. The author is evidently not very familiar with this rare disease. In conclusion, we must accord a large meed of praise to the author, and though the work is of unequal merit, it may yet be confidently recommended as a valuable contribution to the gynækological department of medicine, and not unworthy Professor Schroeder's high reputation.

It will surprise total abstainers and others to learn that, according to Dr. Gutziet, ethyl alcohol is present in the unchanged sap of the fruit of certain umbellifers, the cow parsnip (*Heracleum giganteum*) and the common parsnip (*Pastinaca sativa*) being good examples. It is, however, suspected that the combinations detected may have been present as ethers and been decomposed by distillation.

NURSES AND NURSING.

There are few medical men who have not, in the course of their practice, felt the want of a good nurse—one who can see that their directions are fully carried out, who is able to cope with those little emergencies which are apt to occur during their absence, and one who is not liable, either through blundering or inattention, to thwart the objects which they have in view, or to undo all the good which they may have accomplished. The attention of the public has been recently called to the great scarcity of good nurses at a meeting recently held at the Home of the Metropolitan Nursing Association in Bloomsbury Square, as well as by an able article in one of the leading morning papers. The Duke of Westminster, who presided at the above meeting, and who has always taken a deep interest in the subject, stated that very little had as yet been done, although a quarter of a century has elapsed since the attention of philanthropists was directed to the fact that the suffering, and even the mortality, caused among the lower classes might be very much diminished by the employment of trained nurses. His Grace admitted that the number of nursing sisterhoods had been multiplied within the last few years, and we cannot but acknowledge the admirable working of such charities as that of the Maison Mère, in the Rue du Bach, Paris, of the community of St. Vincent de Paul, of the Dames de la Miséricorde, and of the Dames de Bons Secours. The good which these charities do is incalculable; their representatives are to be found not only in private houses, but in the hospital and in the camp. In the words of a well-known saying, although in a very different sense, they are "ready to go everywhere and do anything." At the same time, we must allow that Protestant communities have been very backward in following the good example that has been set by the Roman Catholics, and, as the Duke said, trained nurses are still a most important want among the poor, and one that has not been met in any appreciable

degree. We trust that by giving greater publicity to such nursing institutions as we have mentioned, among which the one in Bloomsbury Square is likely to take a high rank, there will be a greater demand, and it is to be hoped, a greater supply of these excellent charities. The nurses from some of these institutions are well educated and of good parentage; they fulfil their duties not only well in a professional point of view, but in a quiet and unostentatious manner; they are satisfied with the simplest fare, and they will go to cases from which an ordinary nurse will turn away. All this cannot be made too well known among members of the profession, whose duty it is to encourage this movement, who should endeavour to break down the barrier which religious prejudices unfortunately throw up against the employment of these good and estimable women, and who, moreover, should encourage the foundation of similar charities by Protestant philanthropists. Only recently we have been frequently meeting at the wretched lodging of a dispensary patient one of the Dames de Bons Secours: a better or more devoted nurse we never before met with, and we were glad, although surprised, to hear that her next engagement was at the house of a Protestant lady, to nurse a case which had been given up by the English nurse on account of the loathsome nature of the disease.

But, while on the subject of nurses, we cannot refrain from making a few remarks on the equally important subject of *nursing*, and from a standpoint that has been much overlooked by physicians of the present day. In the course of his remarks the Duke of Westminster said that "long ago he first learnt the important fact that fairly to cope with disease three things were necessary—the doctor, the remedy, and the nurse." His Grace omitted a fourth and important factor, and of which the Father of Medicine himself, were he alive, would have soon reminded him—we mean the *patient himself*. That there is only too much bad and under-nursing is apparent enough; but are we not apt to forget that, under some circumstances, and in some forms of disease, there is such a thing as over-nursing?

In those wonderful writings of Hippocrates—too much neglected now-a-days—and in that portion of them where he treats of epidemics, is to be found this remarkable passage:—"The art consists in three things—the disease, the patient, and the physician; the physician is the servant of Nature, and *the patient must combat the disease along with the physician.*" The sound truth and philosophy of this saying must be admitted by all, and are well entitled to our respectful admiration when we reflect it was the saying of one who lived more than 2000 years ago. There can be no doubt that at the present day we are too apt to ignore the good old practical maxim of the Coan physician. Amid the abundance and variety of our therapeutical agents, the comforts and indulgences of our hospitals, and our anxiety to secure experienced nursing, we are too apt to forget the advantages to be gained by securing, on the part of our patients, implicit confidence in the treatment and remedies employed, a strict compliance with the directions given, a liberal indulgence in those habits and in those emotions of the mind which contribute to recovery and health, a due control over those which are prejudicial to the maintenance of a cheerful and hopeful disposition, and a strong effort on their part to bear up against their sufferings, to divert their attention as much as possible from their ailments, and to resist those inclinations, those habits, and even that tone of thought, the only effect of which would be to retard their recovery. We all know how great is the influence of the mind over the body, but we venture to say that, in practice, this physiological fact is not turned to such good account as it might be. At all events, it is the duty of all those in immediate attendance upon the patient to encourage him to "combat the disease along with the physician;" and in proportion as nurses are able to exercise with discretion this moral and higher control over those committed to their care, the higher and more respectable will be their position in the sick-room, and the greater claim they will have upon the gratitude of the public.

THE QUALIFICATION FOR SURGEONCY TO IRISH COUNTY INFIRMARIES.

The office of Surgeon to the County Infirmaries of Ireland has been regulated for exactly a century since the year 1766 by four successive Acts of Parliatment, respecting the provisions of which a question has recently been raised which will result, probably, in a change in the law which fixes the qualification of candidates. By the 5th and 6th of Geo. III., cap. 20, it was declared "that no person shall be capable of being elected who shall not have served a regular apprenticeship of five years to a surgeon, and have likewise undergone an examination before the Surgeon-General, the Visiting Surgeon, the two Assistant Surgeons, and the Resident Surgeon of Dr. Steevens' Hospital, and the four senior Surgeons of Mercer's Hospital." The candidate was submitted to examination by an independent board, because no surgical licensing body then existed in Ireland, but after the establishment of the Irish College of Surgeons the examination of infirmary surgeons was transferred to them. In the year 1795, by the 36 Geo. III., cap. 9, it was enacted "that no person shall be capable of being elected surgeon to a county infirmary or hospital who shall not have previously obtained 'Letters Testimonial' of his qualification under the seal of the Royal College of Surgeons in Ireland; and that no other qualification or examination shall be necessary to make any person capable of being elected surgeon to such infirmary or hospital." This grant of a monopoly of licensing Irish infirmary surgeons was confined to the College by successive Acts—54 Geo. III., cap. 62, 1814, and 6 & 7 William IV., cap. 116, which made it necessary for the surgeon to lay on the table of the grand jury his "Letters Testimonial" from the College before he could receive his pay. Up to the present the Irish College of Surgeons has enjoyed the undisputed title to its privilege, but circumstances have recently occurred which are likely to result in the repeal of these enactments. Since they were passed other licensing bodies which have as full a legal, if not as good an actual right to grant surgical degrees have come into existence, and two years ago the subject was brought into prominence by a contest between two surgeons for the Tralee County Infirmary. One of them, Dr. Alton, had never held the "Letters Testimonial," but was nevertheless a Fellow, for in the year 1844, when the College obtained its last charter, he

had been co-opted to the Fellowship without examination under the authority of a "Year of Grace" clause in that charter. Dr. Lalor was, on the other hand, the possessor of the "Letters Testimonial" obtained as usual by examination, but he was not a Fellow, and did not require to be one to enable him to seek the surgeoncy. On a poll, Dr. Alton was elected, and Dr. Lalor disputed his right to hold the office on the ground that, though a co-opted Fellow, Dr. Alton had never been a Licentiate. The question for the decision of the Judge was whether the Fellowship did or did not confer all the privileges of the "Letters Testimonial." To settle this issue, the College charter was produced, and it was found that while the section referring to Fellows by examination contained a special clause conferring on them all the privileges of Licentiates, the "Year of Grace" clause, under which Fellows were co-opted without examination, contained no such provision. The clause runs as follows: "Our will and pleasure is that every person so admitted a Fellow of the said College, not being already a Member or Licentiate thereof, shall also by virtue of such his admittance as a Fellow become and be called and be considered admitted as a Member or Licentiate of the said College." In the absence of this proviso from the "Year of Grace" clause, and in consequence of the omission of examination in the case of co-opted Fellows, the Judge decided as follows: "I am of opinion that he (Dr. Alton) is not the duly qualified surgeon referred to through the whole of this legislation; and the language of the charter cannot dispense with the substantial requisites mentioned by former Acts, and which we think applicable to the candidate who applies for this particular situation."

This decision settled the incapacity of co-opted Fellows, but left undeclared the capacity of Fellows by examination who had not previously been Licentiates. In view of a probable vacancy in a county infirmary, application was made some weeks ago by such a Fellow to the Council of the College for a grant of their "Letters Testimonial" under the authority of the clause of the charter which we have quoted above, and the Council, after deliberation, decided to grant the request in this and all similar future cases. It was resolved that the diploma of "Letters Testimonial" should be granted to all who had been duly examined for the Fellowship, and that all such persons should receive both forms of diploma at the time of their passing the Fellowship examination. By this resolution the College has—as far as in it lay—secured to its Fellows all their rightful privileges, but it would seem that the enjoyment of an exclusive right to county infirmary surgeoncies is not long to continue a monopoly in the hands of the College of Surgeons.

The Council of the University of Dublin have passed a resolution that the Board of Trinity College be requested to take steps to remove the disabilities of the holders of degrees in medicine and surgery of the University of Dublin, by which they are excluded from public appointments in Ireland, and, in the case of bachelors in surgery, from the Medical Register.

Mr. Edward Gibson, M.P., one of the University representatives, has introduced a Bill for this purpose, and the Council of the College can hardly hope to contest the point with him. No doubt they will see that the "Letters Testimonial" of the College is no longer the only surgical diploma of repute in Ireland, and that they will have the prudence to yield gracefully a point which could not reasonably be maintained.

THE ADJOURNED DEBATE ON ALCOHOL AT THE MEDICAL SOCIETY.

On the 10th of January the debate on Alcohol was resumed in the Medical Society of London, the chair being occupied by the President, Dr. Routh. The meeting was well attended; but Dr. Benjamin Richardson, who was expected by some to recommence the debate, was absent.

This is the more to be regretted because that gentleman has recently taken up such a decided position against alcohol as a food, that it would have made the debate more complete had he been one of the speakers, and thus been able to explain his views and reply to the criticisms which would doubtless have been applied to them. As it is, however, the debate has been replete with interest to the medical world.

The first speaker was Dr. Milner Fothergill. He thought that alcohol improved digestion, acted as a food, and promoted assimilation. It was very proper in syncope, and, with hot water, was advantageous after exposure. It is a food, for any substance which is oxidised, whether completely or not, in the system furnishes heat or mechanical motion, and is therefore a food. Alcohol in small doses *is* completely oxidised in the body; in large doses it is not entirely so; but what is oxidised is a food.

Dr. Drury preferred the term alcoholic fluids to that of alcohol.

Dr. Lucas considered a stomach unhealthy which did not act without alcohol. If heat be lost by taking alcohol, strength also is lost. This substance should therefore be administered with much caution.

Dr. Crisp, as a teetotaller, thought alcohol a valuable agent in disease. Previous habits of a patient would influence his treatment, for persons accustomed to much alcohol could not get on well sometimes without some of their accustomed beverage. He doubted whether the order of the effects of alcohol on the system could be divided into cerebral, cerebellar, spinal, and medullary. As to the use of alcoholic drinks, they increased the rate of mortality 10 per cent.

Dr. Semple had a middle estimate of the value of alcohol. In typhus fever and delirium tremens it was unnecessary. On the contrary, it was useful in post-partum hæmorrhage in many instances. During the ordinary course of typhoid fever, alcoholic fluids were quite unnecessary; but when the heart's action became depressed, then they were necessary. In delirium tremens, too, provided care were taken to prevent the patient from doing any mischief, it was unnecessary to add alcohol.

Dr. Farquharson drew attention to the adulteration of beer and its maddening effects on soldiers. The carouser in the army did not suffer such ill-effects as the quiet, steady drinker.

Dr. Sibson always gave alcohol in fevers when

the pulse was dicrotic, and he quoted Dr. Anstie's opinion that the arterial tension was a most valuable guide in clinical administration of the remedy, as it showed when to give and when to withhold alcohol. He drew attention to the chronic diseases induced by alcohol, to cirrhosis of the liver, alcoholic degenerations, &c. In cases of kidney disease alcohol was useful to a certain extent in stimulating the kidney to eliminate the poison in the system.

Dr. Leared considered alcohol a valuable agent in obviating the effects of waste in disease, and in dyspepsia.

Dr. Hare, in a moderate speech, spoke of the various advantages and disadvantages resulting from the use of alcohol as a remedy. It might, on the whole, be a question, he said, whether it would not have been better for the race had alcohol not been discovered.

Dr. Lauder Brunton, in reply, stated how posture facilitated brain power in hæmorrhage. Alcohol stimulated the nerve centres of the motor system, forwarded direct influence from the medulla oblongata, and thus contraction or dilatation of vessels were accounted for. He preferred beef-steaks, plus wine, to milk and water in promoting rapid recovery from hæmorrhage. He drew attention to the velvety skin of drunkards, due to the deposition of fat. As digestion fails, thinness supervenes.

It is, we have said, to be regretted that the Society had not the advantage of having its adjourned meeting opened by Dr. Benjamin Richardson, whose Cantor Lectures, delivered before the Society of Arts last year, were such a valuable contribution to this important subject. His conclusions, however, in the published record of his lectures are before us, and read as follows:—

"This chemical substance, alcohol—an artificial product devised by man for his purposes, and in many things that lie outside his organism a useful substance—is neither a food nor a drink suitable for his natural demands. Its application as an agent that shall enter the living organisation is properly limited by the learning and skill possessed by the physician, a learning that itself admits of being recast and revised in many important details, and perhaps in its principles.

"If this agent do really for the moment cheer the weary, and impart a flush of transient pleasure to the unwearied who crave for mirth, its influence (doubtful even in these modest and moderate degrees) is an infinitesimal advantage by the side of an infinity of evil, for which there is no compensation and no human cure."

We have already remarked how important we consider the fact that one of the most popular of our London societies has commenced the debate on the question of how far alcohol is a food or a remedy in disease. The debate cannot fail to be continued in several of the other learned professional reunions in England, Scotland, and Ireland; and whether the speakers on either side be able or not to place the whole truth before us, we shall at least learn what is now thought by the living generation on one of the points of the most vital importance to human welfare.

Some one has recently said that the Anglo-Saxon race is naturally prone to alcoholic stimuli. This, like many other supposed excellencies attributed to that race, may or may not turn out to be a virtue; but of one thing we may be sure, and that is that the drunkenness of our working classes is at present more deplorable than it ever has been in the history of the British nation. Whilst the educated classes are fast leaving off those habits of drunkenness which their fathers were so prone to, there is scarcely any poor man's home that is long free from that desolating vice. The ratio of delirium tremens among women as compared with that among men is, we hear, higher too in our country than in any other; and every philanthropist must look with sorrow on the degraded condition of thousands of our town operatives, who, with excellent wages, can find nothing better to do with the fruits of their hard toil than to make themselves frightful examples of the physiological effects of alcohol upon animal life.

The debate in the Medical Society of London has shown that many of the members of the medical profession at present living among us are themselves practical teetotallers.

If we may judge from the speeches of Dr. Crisp, Dr. Edmunds, Dr. Lucas, and Dr. C. R. Drysdale, these gentlemen seem to think it right to live habitually without even beer or wine; and Dr. Hare's opinion that it would, on the whole, have been better for us all if alcohol had never been used by the race, tends certainly in the same direction.

Dr. Lauder Brunton and Dr. Milner Fothergill seem to be staunch upholders of the view that alcohol is a food because it is partly oxidised in the system; whereas Dr. Richardson, Dr. Drysdale, and others assert that it is not a food at all, or even a drink, in the true sense of these words. Who is to decide after such conflicting opinions? Time alone can heal the disaccord among practitioners as to the value of alcohol in health and in disease.

Notes on Current Topics.

The Professorship of Midwifery in Galway College.

The vacancy caused by the death of Dr. Doherty, to which we referred a fortnight since, is not yet filled, and several candidates, mostly *alumni* of the Queen's University, are in the field. The following gentlemen have actually declared their candidature, whose credentials we give below as they appear in the "Irish Medical Directory:"

Donovan, William, Waterford.—L.R.C.P. Edin. 1869; L.R.C.S. Edin. 1869; L.M.R.C.P. Edin. 1869; L.M. Cork, 1868; Fel. Obstet. Soc. Edin. (Edin. and Cork.) Late Med. Off. Carrignavar Disp., Cork Union. Author "The Dangers of Chloral Hydrate," *Med. Press and Circ.*; "Medical Education," *Ibid.*; "Phymosis," *Ibid.*

Duggan, J., Turloughmore, co. Galway.—L.F.P.S. Glasg. '57; Lic. '70; L.M. '70; K.Q.C.P.I.; Med. Off. Turloughmore Disp.; late Assist. Surg. R.N.; Mem. Surg. Soc. Author "On Cholera," "On Placenta Prævia," "Diagnosis of Scarlatina," "Necrosis of Tibia," and several Translations, *Med. Press.*

Rice, Patrick M., Galway.—L.K.Q.C.P.I. '67; L.R.C.S.I. '67; L.M.K.Q.C.P. '67. (Cath. Univ.; Cecilia-st. School; Mater Misericord. Hosp.) Tempy. Med. Off. Spiddall and Swinford Disps. Contrib. "On the Action of Veratrum Viride."

Cremation.

THE Milan newspapers publish detailed accounts of the cremation of the body of Signor Keller. Among those who attended were representatives of the municipality of Milan, of the provincial and communal sanitary councils, of the learned and scientific professions, together with many distinguished members of Milanese society, and Professors Polli and Clericetti, the inventors of the system of cremation employed. The "crematory chapel" has been built in the public cemetery out of the funds left by Signor Keller for the purpose. To this chapel on the first anniversary of his death were brought the remains of Signor Alberto Keller, in compliance with his will, for cremation. The coffin, having been opened at one end, was placed near the urn, above which a flame was playing, and then by some unseen contrivance the body was conveyed inside the urn and submitted to the action of the fire. The Protestant minister pronounced a discourse in French, contending that neither in religion nor good feeling was there anything opposed to the practice of cremation. Meanwhile, by looking through an aperture in the urn, the persons present could see the body in process of cremation. It was upon a kind of gridiron, surrounded by flames given off from 217 jets of gas; beneath was placed a receptacle to catch the ashes as they fell. To a person looking on nothing was visible of the process but the bright flame which burned steadily over the urn, and a dense column of smoke which escaped from the tower. The ceremony lasted about an hour and a half, at the end of which time the urn was opened and the body was found completely calcined. During cremation no offensive smell was perceived. A second body—that of Signora Pozzi—is awaiting cremation at Milan, but the municipal authorities have determined not to give their consent till they are satisfied as to the result of the experiment.

Chloral in Ozæna.

AT a meeting of the Société de Thérapeutique, M. Créquy strongly recommended chloral as an injection in ozæna, in the proportion of two parts to 250 of water. He places a caoutchouc tube in the vessel containing the solution, and, raising this above the patient's head, allows the fluid to pass into the nose by syphon action. Several members of the Society testified to the utility of the solution as an application in scrofulous and fœtid ulcers, in the eschars produced by decubitus, &c.

A Scene between Doctors.

A PROSECUTION last week against Mr. Slattery, proprietor of a gut factory in Limerick, for causing a nuisance, gave rise to an exciting scene between a magistrate and a witness, both being medical men.

Dr. Barry, the Medical Officer of the Workhouse, gave evidence on the part of the prosecution, and Dr. Parker for the defence, when the following dialogue took place:

Did you observe gas lime on the floor?

Dr. Parker—I did, and I say it was gas lime created the nuisance.

Mr. Leahy—Is not Dr. Barry's opinion as good as yours?

Dr. Parker—A man of my standing at the profession should not be placed on a level with a mere boy; his advice was mere bosh—I repeat it was bosh, Sir.

Dr. Parker was here leaving the table—

Dr. O'Shaughnessy (excitedly)—Before you leave I must again, on the part of the profession, loudly protest against the language you have used towards a young professional man, particularly when you say your age and time of life justifies you in looking down upon a young medical man. Now, Dr. Parker, I am fifty years in the profession. I have practised very largely. I have associated myself during the last twenty years very closely with the leading members of my profession in Dublin, and I heard their opinion daily expressed with regard to the rising professional men of the day, and their opinion is that in Limerick, and in other country towns the young medical men are equal in ability—aye, superior in ability—in scientific, theoretical, and practical knowledge, to some of the eldest bunglers we have in the profession; I hold that a man may be seventy years practising at the profession and be still bungling at it. I hope, Sir, in justice to that young man—I have no particular interest in this case; I will take no part in it because I could not do so in justice to my oath as a magistrate—but I ask you, Sir, not to repeat and have sent forth on the press such langnage—language which I heard universally condemned when used on a former occasion. I know Dr. Barry; he holds a position of trust in this city; he is treating 600 people—the sick poor, and the bone and sinew of our city. I voted for him, and I would not have voted for him if his words were "bosh." I heartily hope, Sir, you will retract that observation.

Dr. Parker—Indeed I will not, and I should be very sorry to look upon you as an authority in the medical profession. No medical man in Ireland would believe it. Your remarks about a man being seventy years at the profession and being still an old bungler applies to yourself, and I hope the press will take that down.

After further medical testimony on behalf of the defendant the case closed, and the magistrates retired to deliberate. After an absence of some minutes they returned into court, when

The Mayor announced that they were equally divided, and he would not himself record his casting vote, as he believed it would be imprudent on his part, he being new in the office of Mayor—"No ruling" could then be entered.

We are bound to say that Dr. Parker's statement respecting his professional brother was neither justified by the facts nor in any respect creditable to himself. In making such an observation in open court he did dishonour to his profession, and allowance may therefore be made for the somewhat unmagisterial ebullition of Dr. O'Shaughnessy.

Medical Purchase in Dublin.

WE referred in our issue of February 2 to a statement made by a contemporary to the effect that "regular money payments are generally exacted from the newly-appointed members of hospital staffs in Dublin;" and considering such a statement neither correct nor just to Dublin hospital medical officers, we took the opportunity to deny the general truth of the statement, and to explain that in some instances in which purchase took place the hospitals were the actual property of the medical officers,—not established by public grants or benefactions, but bought by the money of the medical officers, and therefore in all fairness saleable, so long as thorough competency of the succeeding medical officer is ensured. Our contemporary in its latest issue repeats its former statement, and calls on us to substantiate our denial, which we shall endeavour to do. There are 10 general clinical hospitals in Dublin and 6 public special hospitals, excluding from

the calculation small semi-proprietary institutions which receive no public income except a few subscriptions for the current year. In only 4 out of the 10 general hospitals, and in only 1 out of the 6 special institutions is—as far as we have knowledge—any money consideration given for a medical appointment. Of the 4 general hospitals, 2—the Adelaide and the City of Dublin—were built, established, and maintained within a comparatively recent period by the predecessors of the present medical officers; and in the latter institution the moment that the governors consented to take responsibility for the maintenance of the hospital, the medical officers acceded to an arrangement by which the vested rights will be gradually extinguished and the appointments be made gratuitously. There are therefore only 2 out of the 10 general hospitals in which the purchase of appointments exists under the conditions referred to.

We do not care to defend the principle of purchase, but we cannot say that it has ever worked to the disadvantage either of the patient or the charity. It has never in the least restricted the competition for hospital appointments, because it has always been possible, and, in fact, usual for the poorest candidate to raise the necessary sum and to repay it in a short time by the pupil-fees which he received; and we challenge denial of the fact that recent appointments in purchase hospitals have frequently fell to the lot of young men whose impecuniosity was admitted. If our contemporary desires to apply its mind to the cause of bad appointments in Dublin hospitals, it will be found, not in the purchase system, but in the fact that in certain institutions the selection of a new comer is made by the medical officers who are already in possession.

A New Physical Force.

Professor Crookes' lecture at the Royal Institution on Friday last, "On the Mechanical Action of Light," demonstrated in a most remarkable manner a new motive power in light. His experiments were of a most delicate and complicated description, and from what we saw we are inclined to believe it quite possible that the production of motion by light may lead to a complete revolution in the theory of its undulatory movement. The rotation of the earth may indeed in great measure depend upon this marvellous force. The learned lecturer commenced by observing that all the physical forces render their action perceptible by the production of motion, but that light had never been directly converted into mechanical motion until the experiments had been devised which he had to bring before them that evening. Once in attempting to weigh bodies in an approximately perfect vacuum, he witnessed anomalies for which he could not account, but upon which information had been thrown by his more recent discoveries. He found that the light of a candle would attract an arm of pith suspended in an imperfect vacuum, but repel a similar arm suspended in the very perfect vacuum obtainable only by the aid of the Sprengel pump. Of this pump he exhibited a most perfect and improved specimen, so perfect that it would produce a vacuum through which the electric spark would not pass. In all his experiments he had been much indebted to the industry and extraordinary powers of glass-blowing possessed by his assistant, Mr. C. Gillingham. He then described the construction of his "radiometer," in which pith discs, at the ends of glass arms balanced on a pivot, were made to spin round rapidly under the influence of either light or heat, and explained that this propelling force of light was not so weak as he had once supposed. Instead of radiometers in which all the moving parts weighed sometimes as little as a quarter of a grain, he found that he could make the instruments carry little iron magnets, and he exhibited one in which ten discs of pith were required to carry round one magnet. Outside the bulb of this instrument was a magnetic arm, which was attracted every time one pole of the magnet inside the bulb came near it, and the consequent "bowings" of the magnet outside were made to convey electrical impulses to a Morse telegraphic instrument, whereby a series of dots were printed upon a slip of paper, and the more rapid the rotation inside the bulb the closer together were the dots. Thus his radiometers had been made self-registering and suitable for meteorological purposes. He also pointed out that no good photometer had ever been made, and he exhibited apparatus infinitely more exact for measuring the illuminating power of gas, or any kind of light, than those founded upon the supposed unvarying illuminating power of the very untrustworthy "standard candle." After many experiments magnified and projected on a screen by the aid of the electric lamp, he exhibited one of his latest instruments, in which he directly measured the mechanical force of the impact of light, not its weight, for the experiments did not remove light from the class of imponderables. By means of the force of torsion of a very fine filament of glass, brought into play against an iron weight of one-hundredth of a grain, all in vacuo, he could so adjust a mirror to a zero point that it would move when parts of the apparatus were submitted to the action of light; thus, he proved that the push of a candle six inches off amounted to ·00162 grain. By calculation he estimated that the pressure of sunlight on the earth was not less than 2 cwt. per acre, 57 tons to the square mile, and 3,000 millions of tons upon the whole earth, all this power acting in opposition to the force of gravitation. In conclusion he said that the results exhibited had been obtained in consequence of his examination of an anomaly contrary to all ordinary experience. Anomalies were of the utmost value to men of science; they were gateways leading to new researches, and to the establishment of reputations.

The Irish Pharmacy Act.

A deputation from the North of Ireland Chemists and Druggists' Association, consisting of Messrs. Dobbyn and Hazlitt, of Belfast, waited by appointment on the committee of the Chemists and Druggists' Association of Ireland, at the rooms of the latter, 172 Great Brunswick Street, on Wednesday, 26th January, for the purpose of asking co-operation in requesting Government to make some amendments to the Pharmacy Act. The following members were present: Mr. E. M. Hodgson, President; Professor Tichborne, V.P.; Mr. W. Hayes, hon. sec.; Mr. S. Oldham, hon. treasurer; Messrs. Grindley, J. T. Holmes, J. O'Brien, and R. Simpson. After considerable

discussion it was arranged that a joint deputation from the two associations should request an interview with the Chief Secretary.

Fatal Result of a Football Match.

An inquest was held at Moss Side last week concerning the death of Joseph Henry Ison, 16 years of age, who was killed in a football match played at Chorlton-cum-Hady on Saturday, between the Egerton Football Club and the Fallowfield Wanderers. The deceased, who was one of the most prominent members of the Egerton Club, became insensible at the close of the game, and remained in that state until five on Sunday morning, when he died. He had sustained severe internal injuries during the game. The jury returned a verdict of accidental death, and strongly recommended that the practices of "charging," "butting," "scrimmaging," and catching by the legs, as practised in the game of football, should be abolished.

Epidemic of Typhoid Fever.

The village of Eagley, situated about two miles and a-half from Bolton, is at present suffering from an epidemic of typhoid fever, which has laid prostrate more than 100 of the inhabitants. The medical officer, Mr. Robinson, suspected that the whole of the affected persons received their milk from one farm, and accordingly procured samples and forwarded them to Mr. Sergeant, medical officer of health for Bolton, and to Professor Roscoe, of Owens College, Manchester. The former has not yet made a formal report, but has expressed an opinion that the impurity of the milk is the sole cause of the epidemic.

Pharmaceutical Purity.

The virtuous indignation of the pharmaceutical periodicals when the public analyst for Sheffield exposed the dishonesty of dispensers in that town will be in the memory of our readers. The official organ of the English Pharmaceutical Society was horror-stricken at the audacity of such an accusation, aud called for speedy vengeance upon the analyst, and adopted altogether a tone of injured innocence rather amusing to those who know anything about the purity of the English drug trade. As an instructive commentary upon our contemporary's indignant asseverations, we find in its columns last week the following letter from Messrs. Howards, the eminent quinine manufacturers :—

Sir,—We beg to enclose copy of an astounding proposition, contained in a letter received from a foreign merchant, to which we of course sent a suitable reply.

Howards and Sons.

"Yesterday I received a letter from one of my clients abroad, in which he states that your quinine, which I bought from you lately, although it is pure and a good quality, but the price is so high as he cannot sell it ; but you must bear in mind that by saying high price I do not mean it is dear, but the article is too good for the market. There is a French sulphate of quinine which goes largely to our market and sells from 30 per cent. to 35 per cent. cheaper, and the secret of this being sold so cheap is this, that each vial contains a trifle more than half ounce, and 60 per cent. is pure quinine and 40 per cent. is magnesia, and it is mixed in such a manner as no one can tell that it is adulterated except by a chemist analysing it. In our country round the year, especially in summer, a large quantity is consumed, and I can buy continually from you largely if you will consent to make this alteration on purpose for me—viz., half ounce vials containing 65 per cent. pure quinine and 35 per cent. magnesia, and what will be your lowest quotation on the base, and if possible please send me two or three vials of half ounce each, two mixed as above and two pure, as I want to forward them to two clients of mine as samples, and if they meet their approval they are sure to place me a large order. Hoping you will attend to this request and favour me with an early reply, I remain, etc.

"Dec. 30, 1875."

It is evident that Messrs. Howards' correspondent did not know who they were dealing with, the character of that firm being entirely above suspicion ; but it is equally evident that such a proposition would not be made if he who made it had not good reason to know that there are drug manufacturers who would entertain it and pharmaceutists who would purchase the false quinine.

A Medical Lord Mayor.

The Lord Mayor of Dublin, Dr. G. B. Owens, entertained his Grace the Duke of Abercorn, as her Majesty's representative, as well as the leading citizens of Dublin, at a banquet in the Mansion House on Thursday last.

In the dispensing of the civic hospitalities the Lord Mayor took care to recognise especially the claims of his medical brethren to his consideration, and the compliment he paid his profession in this way was acknowledged by the presence of all the leading representatives of medicine and surgery in Dublin. The toast of "the Medical Profession" was advanced to an earlier period of the entertainment than it has usually occupied, and was responded to by Dr. Gordon and Dr. Edward Hamilton, the Presidents of the Colleges of Physicians and Surgeons. In ascending the Mayoral chair Dr. Owens has shown a beneficial example both to his metropolitan brethren and the citizens of Dublin, for he has proved that active medical practice is no bar to the praiseworthy discharge of public duty, and that the claim of a physician or surgeon to civic honour will be recognised by the citizens whenever high social qualities accompany administrative ability.

The Queen's University in Extremis.

Our readers know already enough of the administration of the institution which claims to be *the* National University of Ireland—the Queen's—to be aware that its executive body are not either in matters of medical education, or of public business, the largest minded conclave to which such a trust could be confided. Its acts and views have always, indeed, borne a greater resemblance to those of a petty huxter than to the proceedings of a liberally-minded and progressive executive aid. It has seemed impossible for the managers of the University to see beyond the narrowest wants of the little oligarchy which they administer. We have—as we think, in the fairest and most candid spirit—entered lately into the merits and demerits of the course of study accepted by the Senate for the University Degrees, and have been obliged—as any unprejudiced journalist who desires to maintain a high standard of education in the profession must—to condemn the extreme meagreness of that curriculum. We did not writ for the object

stroking down the graduates of the University, but to tell the honest truth; and the result of our remarks upon the executive of the University, and upon a few of the less liberal-minded of its graduates goes far to justify our apprehension that the educational level of the University was not such as to develope large-mindedness amongst its *alumni*. The managers of the University have found no better reply to our remarks than to transfer their occasional advertisements to the columns of periodicals which are seldom seen in Ireland, and a few of the graduates follow the admirable example set them by their superiors by "stopping their journal,"—bah! Is it the Queen's University idea of independent journalism that its tongue can be silenced in proclaiming the truth by the withdrawal of a subsidy of a pound or two per year? We are conscious that the mention of such petty irritability of temper is hardly fit for our pages, but the facts are not without their use in illustrating the intellectual position of the University which clamours so loudly for the public confidence. We feel complimented by this display of irritation on the part of the University, because it makes us aware that our strictures upon its educational management hit the mark and produced an effect upon the medical public. We would feel greater regret for the necessity which obliged us to speak upon the subject if we saw that the representatives of the University had sense and temper to hear the truth about themselves.

The Effects of Indulging in the Subcutaneous Injection of Large Quantities of Morphia.

In a recent issue of the *Allgemeine Wiener Medizinische Zeitung* a case is related which shows in a striking manner the remarkable and disastrous effects that may arise from the frequent use of large morphine injections.

The patient, who was himself a medical man, was under the care of Professor Weinlechner, of Vienna. In consequence of the great pain which continued long after an attack of traumatic periostitis of the left shin-bone, he had recourse to the daily subcutaneous injection of morphia. In July, 1867, he used a syringeful of the injection daily, and owing to the frequency and severity of the paroxysms of pain he increased this quantity until by the end of the first year from commencing the injections he used every day as much as ten grains of morphia. At first the injections were followed by sleep, but afterwards by only a feeling of repose. In the beginning of the second year the pains in the shin disappeared, but were followed by great irritability and muscular tremors, especially in the lower extremities. In consequence of the numerous injections that had been used, a number of abscesses made their appearance in various parts of the body, and the suffering arising from these was a fresh pretext for renewing the injections. To such an extent was this practice indulged in that the daily quantity of morphia now amounted, in the third year, to twenty grains, in the fourth year to thirty grains, and in the year 1873 to as much as forty grains! Since the latter period the patient has been confined to his bed. When visited by Professor Weinlechner he was so covered with abscesses that there was scarcely a sound portion of skin. He was, moreover, reduced to a skeleton, and the skin was so tightly contracted over his emaciated extremities that it could not be raised into folds for the purpose of injection, and both knees were bent at right angles, in consequence of the contraction of the flexor muscles.

With respect to the treatment, the morphia injections were at once given up, a little morphia given internally, or the inhalation of chloroform being occasionally resorted to for the sake of producing sleep. The abscesses were opened, and healed under very simple treatment. The contracted legs were stretched while the patient was under the influence of chloroform, but without any permanent success; nor was a resort to mechanical means at first attended with any better result. At last, and although there was not the slightest reason for suspecting that there was any syphilis in the case, large doses of iodide of potassium were prescribed, and with astonishing results. The painful spasms of the lower extremities completely ceased, sleep and appetite returned, the patient gained flesh and strength every day, and nothing remained but to overcome the contraction of the limbs by persevering in the use of mechanical extension.

Certificate Reform in Dublin.

The University Council of Trinity College, Dublin confirmed last week the resolutions of the Board to enforce a full attendance upon hospital and clinical lectures on the part of candidates for University degrees, and this resolution having been adopted in principle by the Irish College of Physicians, needs now only the assent of the Irish College of Surgeons to make it medico-educational law. The Queen's University will probably continue to take any certificates, *nulla fide* or *bonâ fide*, which are offered to it, for, strange to say, the *soi-disant* national University, which is supported by the State, is on all occasions the last institution either to initiate reforms or to yield to the pressure of public opinion on any point which would interfere with the profits of the diploma market. The next step which the University of Dublin must take for its own protection and that of the colleges which follow its example in requiring *bonâ fide* attendence will be to bring the subject under the notice of the General Medical Council in June, and enlist their authority in putting a stop to the sham certificate system in Ireland. Doubtless the representatives of the Scotch corporations and the Queen's University will contest, *dentibus et unguis*, any effort to reform the present lecture certificate system, but it is not likely that they will succeed in maintaining it under the heavy blow which it has sustained from the University of Dublin and College of Physicians, and which will, we anticipate, be followed up by the Irish College of Surgeons before long.

The Council of the University of Dublin has referred to the Professors the resolutions adopted by the Board of Trinity College in reference to the appointment of "extern" examiners and the creation of a new degree in midwifery, and as the Professors will in all probability report in favour of these resolutions, they may now be accepted almost as law. The following are the resolutions on which the Professors are asked to give their opinion:—

I. Two extern examiners shall be selected by the senior

lecturer and the medical registrar, to take part in the examination for the M.B. degree.

II. That in due course of time surgery and midwifery should be removed from the M.B. examination altogether.

III. That a licence should be conferred in midwifery as well as in surgery, the examination for such licence to be of a high scientific order, including embryology and physiology, as well as the practice of midwifery.

IV. That the senior lecturer, in conjunction with the medical registrar, be directed to recommend examiners to assist the professors in the medical school at the examinations in botany, physics, chemistry, and materia medica.

The Hospital Saturday Fund.

THE first meeting of the board of delegates for carrying out the Hospital Saturday Fund for the current year was held by permission of the governors, on Saturday last, in the Board Room of King's College Hospital, and was very largely attended by representatives of trade and benevolent societies of the *employés* of large metropolitan firms. Several treasurers of hospitals were also present. Captain Mercier was, in the first instance, elected chairman of the meeting, and subsequently re-elected as chairman of the fund for the present year. Mr. N. H. Hoare was re-elected treasurer, Mr. C. O. Humphreys as honorary solicitor, Messrs. Hoare and Co., of Fleet Street, bankers, and Dr. Vincent Ambler and Mr. Henry Johnston as honorary secretaries. The trustees and council for the year were also chosen, and a discussion arose as to the day which should be fixed upon for this year's "Hospital Saturday." It was ultimately resolved to fix that day fortnight for the settlement of the question.

THERE will be no Hunterian Oration this year at the College of Surgeons, where it is now delivered biennially. Sir James Paget will give it in 1877.

THE Report of the Royal Commission on Vivisection was presented on Tuesday week to the House of Commons, and ordered to lie on the table.

MR. MELDON has obtained leave of the House of Commons to introduce a bill to alter the constitution and government of county infirmaries in Ireland.

LEAVE has been given to Sir H. Johnstone to bring in a bill in the House of Commons to repeal the Contagious Diseases Acts, 1864, 1866, and 1869.

THE Board of Trade have ordered an inquiry to be held into the existence of scurvy on board Mr. Bates's ship *Royal Sovereign*, which recently arrived at Falmouth with a number of the crew suffering from that complaint.

DURING the month of January the water supplied by the Chelsea, Grand Junction, and Lambeth Water Companies was turbid, and contained living organisms and fungoid growths.

HER Majesty the Queen has signified her intention of opening in person the new wing of the London Hospital on the 7th March. The wing has been built mainly by the munificence of the Grocers' Company, at a cost of about £20,000.

LAST week the wife of a carpenter living at Hastings was delivered of twin girls united together at the chest. The infants, which were of full period, and well developed, did not survive their birth. A photograph of the children has been taken.

A LADY has offered to contribute £1000 towards laying down wood pavement along the frontage of Middlesex Hospital. It would require 1,740 superficial yards, and would cost £1,423. The offer was accepted by the Marylebone Vestry, and the work will be carried out forthwith.

BY the will of Miss Cort, who died some few weeks since at Kirkby, the Liverpool charities are the recipients of another large bequest, the total amount of which is £25,500, and the sum is to be divided among twenty-four institutions, eleven of which receive each £2,000, two others £1,000, and the balance is apportioned in small amounts among thirteen others.

THE subject selected for competition for the Hastings Gold Medal, value twenty guineas, offered by the British Medical Association, for 1876, is "Diphtheria, its Pathology, Diagnosis, and Treatment," and the award will be made at the annual meeting of the Association in that year. The sum of £25 has also been presented to the Association to be offered for the best essay on "Pyæmia."

DR. MINTER, whose term of office at the Naval Hospital at Stonehouse was unexpectedly brought to a close by the issue of new regulations, is (says the *Western Morning News*) to receive some compensation for the loss of his appointment. It was at first refused by the Treasury, but the Admiralty having again represented the case, £100 has been awarded.

ON Saturday last the Lord Mayor of London presided at the reopening of the Royal Infirmary for Children and Women, in the Waterloo Bridge Road. The institution has long since become too small for the demands of a densely-populated district, and the committee of management have now increased its capacity to fifty beds, converting the roof of the new building into a playground for the little patients. This has involved an outlay of £3,700, of which nearly the whole has been subscribed.

DR. WILSON, the medical officer for Warwick, in his report upon the sanitary condition of the town, refers to the excessive infant mortality, which last year equalled 176 per 1,000 births, and he states that many deaths attributed to the wasting diseases of childhood were really due to starvation and neglect—or, in other words, to culpable homicide. He adds that Warwick was open to the stigma of being a "Herodian borough."

BRIGHTON maintains its pre-eminence as being the most healthy of the twenty English towns of which the Registrar-General now takes cognisance in his returns.

Last week the rate in Brighton was 14, whilst at Manchester and Bradford it was as high as 34 per 1,000. In London the rate was 26·5, the number of deaths 1,771, being 134 above the average. This excess is chiefly attributed to the prevalence of whooping-cough and diseases of the respiratory organs.

NOTICE has been given that the University of Glasgow will, in March next, appoint additional examiners in medicine under the system introduced by an alteration of the regulations for degrees in medicine contained in ordnance approved of by Her Majesty in Council. The divisions and subjects of examination are—1. Anatomy; 2. Chemistry and Materia Medica; 3. Botany and Zoology; 4. Physiology and Pathology; 5. Practice of Medicine and Clinical Medicine; 6. Surgery and Clinical Surgery; 7. Midwifery and Medical Jurisprudence—so that seven examiners will be appointed. Of those first appointed, two shall be appointed for the term of three years, two for four years, and the remaining examiners for the term of five years.

The annual fee of each examiner is £40.

A FEAT almost parallel with that of Captain Webb has been performed by an American pedestrian named Weston, at the Agricultural Hall, last week. He undertook to walk 115 miles in 24 hours, *i.e.*, very nearly five miles an hour for one whole day and night, and only failed by six miles, having kept going for the 24 hours, and accomplished 109 miles. He would have won his laurels only that after 15 hours' unremitting walking he was obliged to take a rest for nearly an hour in consequence of vertigo and internal pain. How he kept up afterwards was a marvel; he was at times evidently much distressed; his face was intensely cadaverous, and towards the end of his task he looked fully ten years older than when he commenced. The whole time of the walk he was kept up by constant refreshment. An Englishman named Perkins attempted the same task, but broke down utterly beaten at the 65th mile.

Correspondence.

INDIAN MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The time is again almost at hand when the youth of the profession will rush in numbers to the India Office in order to ascertain if they have obtained places for the above service, and those who do so will consider themselves very fortunate; but they will find on coming out here that they have been misled and completely sold, and that there is great discontent in all grades of the service. They will expect to draw 450 rupees a month on passing the required examination in Hindustani, and getting charge of a native regiment, as stated in the India Office memorandum, but they do not as a rule draw this amount before three, four, or more years' service.

On coming out here the young surgeon gets knocked about all over the country, doing what is called "general duty"—viz., taking charge of a cholera camp in the jungle or bazaar, doing the work of a dispensary or hospital, where there is an epidemic of some sort. For this he must keep a horse or hire a vehicle; he must rent and furnish a house, get a retinue of servants. He is often at work the whole day, is frequently called up at night, and for all this he draws only 282 rupees 10 annas a month, which is insufficient to cover his expenses, so it is very common to find even an unmarried surgeon of several years' service in the hands of the soucars or money-lenders of the country. When one of these epidemics ceases in one place, he finds himself ordered off to the seat of another; so he has to sell his furniture, &c., at a great loss, and buy another lot when he arrives at his destination. After a variable time he gets an acting appointment, for which he draws half allowances—viz., 100 rupees for a native regiment or dispensary, or 75 rupees for a wing. In order to take up this sham appointment he has often to pay his fare by rail or road for hundreds of miles; and it is only in the Indian service that this customs exists. When he holds this acting charge for a few weeks or months, he again finds himself on general duty, in order to necessitate his paying his fare to take up another of the same kind. In this unsettled state he remains for years, often having spent hundreds of rupees in travelling on duty. He is obliged to keep a horse for parade, to provide himself with tents, and to march with troops, for which he gets no allowances now. Even when he becomes a surgeon-major he is still a slave; as there is only one medical officer with a native regiment or at a station, he cannot take his privilege leave unless he provide a substitute, and this is impossible in out-stations, even if he offered more than his actual pay; so he is obliged to work year after year in a lonely and very often unhealthy place. The common drudgery of the poorest Irish dispensary is nothing compared with doctoring the natives of this country, who are subject to so many deadly maladies.

The relative rank of Indian medical officers is very poor indeed. A surgeon-major of twenty-five or more years' service has generally three senior to him of the five or six officers in a native regiment. In civil employ he is subjected to snubbing from "local fund boards" (principally composed of natives), he is worried by civil servants and officials of different kinds. A deputy surgeon-general does not get higher relative rank than a lieut.-colonel while on the active list; this is a very low grade in the native army; and as there are only a few in each presidency, but a very small proportion of the medical officers in the service have a chance of obtaing even that rank.

The pensions average less than half what they were when supplemented by the old fund, tentage allowance, head money, and horse allowance have been stopped, except in cavalry regiments, where horse allowance alone is given.

The other day the Madras Government threatened their medical officers because a few in the presidency town drew up a very moderate scale of fees to be paid by those able; but this was quite unnecessary, as nearly all the Europeans in the country are entitled to gratuitous medical attendance, and the natives get treated at the dispensaries or at their own houses, if necessary. There are a few men in the three presidency towns who occasionally get fees, but these are men who have been more than thirty years in the service, and have never received a fee, so private practice as a means of augmenting the miserable pay of a medical officer under the new system need not be taken into account.

The market value of the rupee has gone down from 2s. 3d. to very little more than 1s. 9d., and everything has become so expensive lately that it does not represent in this country more than a shilling does at home.

I am afraid I have already trespassed on your space too far, otherwise there are many things I could bring forward to show that the service exists on the good name it acquired in the East India Company's time.

Your obedient servant,

POVERTY IN THE GORGEOUS EAST.

THE DENTAL PROFESSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is satisfactory to find that at least one of the medical papers is possessed of accurate knowledge respecting the politics of the dental branch of the profession, and is capable of clearly and fearlessly expressing itself on the different aspects of the subject. In the first place, with regard to the rampant quackery which as you have shown is able often to purchase the editorial endorsement (so to speak) of the leading newspapers as a voucher to its false statements.

The MEDICAL PRESS is the sole paper that has dared to denounce in plain language iniquities of this kind. A newspaper of the present day sets itself up always as a preacher of political and social morality; and surely no such preacher can consistently support himself by gains derived from the practice of fraud and cruelty. What would be said of a public preacher of religion who, whilst inculcating obedience to the fundamental principles of morality, was himself living upon rent knowingly obtained from receivers of stolen goods or keepers of infamous houses? And what must be said of those organs which support themselves by lending their columns to the vile purposes which you have denounced. With regard to quack dentists, it is well known that many of these are engaged in a system of extortion and terrorism exactly the same as that carried on by quack doctors; this system has been exposed in your columns recently by the report of cases from the law-courts. Such cases are, however, rarely published; nor do they, in fact, often come to trial. The quack almost invariably withdraws if the victim resist, and he offers compensation when attacked for his malpractice. I enclose a subpæna and correspondence between myself and the attorney in a recent case, in which a dental quack paid heavy damages and the costs of action rather than let the case go into court: and such cases are not uncommon. I have, however, little doubt (such is the boldness of these gentry) that ere long one of them will go a step too far, and will either find himself pilloried in the witness-box or in the dock, and give rise to an exposure which will do much to enlighten the public.

The dental profession must also thank you for your early recognition of the mistake which certain members are making in endeavouring to establish a new society. It is rather rich that these gentlemen should find the Odontological Society not good enough for them, seeing that that Society comprises many eminent men, and some (and these the most active among the members) whose scientific reputation is, in the broadest sense, world-wide. The Odontological Society has consistently worked wisely, liberally, and successfully in the directions in which the new society purpose moving. The new society, I venture to predict, will not withstand the good sense of the majority of educated dentists, and if it come to anything, will form merely an insignificant clique capable of doing little harm and no good.

I am, Sir, your obedient servant,

M.R.C.S., L.D.S.

"HASTINGS WATER SUPPLY."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As one of those who have taken an active part in urging a good supply of water for Hastings and St. Leonard's, permit me space for a few words on your last week's note.

It is evident, from the observations recently made in your own and other medical journals, that the facts relative to the water supply here are very imperfectly known. An agitation was commenced two years ago to obtain a better supply. In the interval, some of the surface sources have been given up; three new wells—each yielding a large quantity of pure water from the sandstone have been sunk; and new springs have been appropriated in the Fairlight district. The Water Committee of the Council has been constantly engaged in making improvements, and it met the public agitation raised by calling in Mr. Topley, to report upon the geological probabilities as to other sources. That gentleman produced a most valuable report, and his recommendations are, as far as practicable, being acted upon. To show that the rates and ratepayers have not been spared, it may be mentioned that £31,000 have actually been borrowed within twelve months for water purposes; and an application is now before the Local Government Board for £10,500 more, to carry out further improvements. Knowing these things, I have felt myself justified in withdrawing all opposition; and I also think I am only acting in fairness to the Water Committee in addressing you in its defence.

Your "Note" says, "The imperfect water supply of Hastings is producing a good deal of dissatisfaction among the ratepayers." That opinion was probably founded on statements made at the late proceedings before Mr. Morgan, who came down to make the usual inquiry before the Local Government Board gave sanction to borrow the money. Three or four gentlemen did complain of inadequate supply. But it was also stated that they lived on a high hill, above the level of any reservoir, and that one of the purposes of the loan was to erect new steam engines to pump a daily supply to those high levels. Apart from this complaint, the "dissatisfaction" rests with something under half-a-dozen persons—as small a number as is likely to be found in any population of 30,000 or 40,000.

I cannot let go, without some explanation, the statement that "the Town Council holds out against the constant water service." Both publicly and privately, the mouthpieces of the Council have stated a desire and a willingness to give the "constant service" system a trial. Until the new works now in course of construction are completed there is neither pumping power nor water enough to do so. It is intended to make a partial trial of the system as soon as the means to do so exist.

I have already extended my letter too far, or other points in the water question might be taken up. "The medical men of the neighbourhood" can do a great deal of good, in forming public opinion; but harm may be done if that opinion be formed on preconceived notions, without due inquiry and thought. That "the health of Hastings at the present time is not up to the standard" cannot arise from anything connected with the water, because there has been an undisputed improvement in quality and quantity for some time past. My own inquiries in vital statistics point to a very different origin, upon which I must not here enter.

I am, Sir, obediently yours,

Hastings, Feb. 3, 1876. J. COGSWELL.

[It is not for us to advise the Town Council of Hastings whence or how to obtain water of good quality and sufficient in quantity for the maintenance of cleanliness and health. We shall, however, consider it our duty to criticise any shortcomings on the part of the Council in regard to sanitation, and should the health returns be not up to the standard, we shall not fail to make it known to the members of the medical profession, who in turn will advise their patients to seek a more healthful resort.]

DOCTORS' FEES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I expected long since to have seen through the columns of your journal some practical expression of thanks to Surgeon H. G. Croly from his metropolitan medical *confrères* for his pluck and determination to uphold the dignity of our profession in compelling by legal means one of his patients to pay him ample fees for ample services. I consider that the most eminent in our profession would, I fear, clutch at the two hundred guineas which Dr. Croly's patient offered, and cry "*satis est*," rather than risk the result of legal measures by proving to the world that the doctor is not to be humbugged. For my part, Sir, I find that since Dr. Croly succeeded in compelling his patient to pay him the full amount of three hundred guineas that a valuable lesson—a lesson of great importance—has been taught to my clients in the country. Now-a-days the humblest cottager or farmer makes himself thoroughly acquainted with the news of the day, and has at his fireside every week a weekly newspaper. There they learned that a patient had to pay three hundred guineas to his doctor, though the latter was not obliged to ride "o'er hill or dale," or wade through sludge or mire to earn them. I, as well as every other doctor in the country to whom I have been speaking on the subject, can *now* evidently see a greater willingness on the part of our patients to pay substantial fees; and I would strongly urge every medical man, those in the remote country parts as well as those in the metropolis, to supply himself with a report of the law proceedings; and if the patient from whom he demands a sum of money as fees shakes his shoulder and says the amount is too much, to at once invite him to see if the jury considered Dr. Croly's demand was too much. The doctors in the country feel thankful to Dr. Croly, and we consider he deserves the same from the profession *in globo*.

I am, dear Sir, yours truly,

MEDICUS IN RURE.

TESTIMONIAL TO STROMEYER, OF HANOVER.

A PRIVATE meeting of distinguished hospital surgeons was held on Monday last, at 18 Park Street, Grosvenor Square, W., to consider the propriety of joining in the movement now going on in Germany to celebrate, on April 6th next, the fiftieth anniversary of Dr. Stromeyer taking his degree in Göttingen. The following gentlemen were present: Sir James Paget, Messrs. Prescott Hewett, Hilton, Curling, White Cooper, Spencer Wells, W. Hulke, J. E. Erichsen, R. Liebreich, John Gay, T. Holmes, W. Adams, and W. MacCormac. Dr. Little in the chair.

An explanation of the preliminary steps taken having been made by Mr. MacCormac, and letters from several gentlemen very cordially supporting the movement having been read,

It was moved by Sir James Paget, and seconded by Mr. Erichsen, and unanimously resolved:—

1. That an address be presented to Dr. Stromeyer, expressing the congratulations of the signatories to it on his long, active, useful and honourable professional career, as shewn by the results of his discovery of the value and safety of sub-cutaneous surgery, by the high tone of his surgical writings, and by his persistent efforts to improve the principles and details of surgery, especially as applied to gun-shot and other wounds received in war, as well as of military hygiene.

2. That Dr. Stromeyer be requested to sit for his bust, to be executed in marble by the most able German sculptor he may select.

3. That a subscription list be opened to defray the expense of carrying out the above objects; that no single subscription shall exceed two guineas; and that subscriptions be not received from persons who are not members of the medical profession.

4. That the substance of the proceedings and of the resolutions which may be adopted on February 14th be announced to the profession at large, by advertisement in the Medical Journals, and that the support and contributions of the profession be solicited.

5. That W. J. Little, M.D., and William MacCormac, Esq., F.R.C.S., be requested to act as joint Treasurers and Secretaries.

It was further moved by Mr. Prescott Hewett, and seconded by Mr. Curling, and unanimously carried—

That the gentlemen present be requested to act as a committee together with Sir William Fergusson, Messrs. Bowman, Erasmus Wilson, Baker of Birmingham, C. Bader, and Dr. Hermann Weber, who had previously signified their desire to co-operate.

Dr. Little, Mr. Spencer Wells, and Mr. MacCormac were requested to act as an Executive Committee, to give effect to the resolutions agreed to, and to receive the subscriptions of those desirous to contribute.

THE MEDICAL INSPECTORSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

DR. CROKER KING having been appointed to the office of Medical Commissioner, the Inspectorship thus becomes vacant, for which several names are already mentioned; amongst others, those of Dr. Whistler, of Bray, and Dr. Kerans, of Ahascragh, in the co. Galway, both of them well-known and experienced Poor-law medical officers, and in this capacity alone possessing strong claims. We hope that no Inspector will be appointed, no matter what his other qualification may be, who has not followed the plough in the work of the Poor-law Service. Of such men perfectly qualified for the position there is no lack, and it would be intolerable if their claims to promotion were ignored in favour of a *protégé*, however high his family qualifications may be.

Royal College of Surgeons of England—The following gentlemen passed the required examination, and received the diploma in Dental Surgery at a meeting of the Board of Examiners on the 8th inst., viz.:—Messrs. Frank O. Adams, Budleigh Salterton, Devon; Walter S. Burrows, New Road; John Alexander Gartley, Sackville Street, Piccadilly; Middleton W. Halliday, Nottingham; Ernest Edwin Jewers, Plymouth; Francis Austin Sayles, Margaret Street, W.; Frank Strickland, Boundary Road; and William H. Woodruff, Leamington.

Army Medical Department.—A fortnight since we referred to the postponement of the examination of candidates for the Department, asking at the same time the question whether the step was not owing to a paucity of candidates owing to the unsatisfactory way the profession was treated. It appears that we exactly hit the nail, for on Monday evening in the House of Commons, replying to Dr. Lush, Mr. Hardy said it was true that for forty vacancies in the Army Medical Department there had been only twelve candidates, and in consequence the examination, which should have taken place to-day, had been deferred. He had laid before the Department which must be consulted before he could bring any measure under the consideration of the House a proposal which he believed would remedy a great many, if not all, the present difficulties in connection with the Army Medical Department.

Royal National Hospital for Consumption, Ventnor.—The annual meeting of the governors of this hospital was held on Friday last, the Right Hon. Viscount Eversley, in the chair. Mr. Ernest Morgan, secretary, read the report and the yearly statement of accounts, which were satisfactory. The committee stated that all the houses contemplated in the original design had now been erected, and that they only await the receipt of sufficient funds to furnish and open the last four houses built. The hospital had been always fully occupied, and there were at the present time over 50 applicantson the register who could not be accommodated for want of room. The medical report, read by Dr. Arthur Hill Hassall, stated that the improvement in the health of the inmates had been very great. Out of 415 patients only 18 had died, or 4 per cent. The committee appealed for a continuance of public support, to enable them to open the remainder of the houses, and for the maintenance of the large establishment at Ventnor, comprising more than 100 inmates.

The London Fever Hospital—At the annual meeting of this charity, held on Friday last, the report of the committee showed that the year had been marked by a very severe attack of scarlet fever, and that the institution had had 710 cases of persons attacked with that disease, besides 68 cases of enteric fever, typhus, and other diseases of a fever character. The committee drew attention to the fact that the institution afforded means of isolating from the family circle those members of the upper and middle classes who might be attacked with diseases of this nature, by giving private rooms, and it opened its doors to the gratuitous admission of persons of the trading and working classes who were naturally averse to being classed as paupers, and sent to the metropolitan asylum. The Earl of Devon, as president, spoke warmly of the services of the institution, and expressed his deep regret at seeing that this year it had had to exceed its income, in providing for the public welfare, to the extent of £4000.

Vital Statistics.—From the Registrar-General's returns we learn that during last week 6,014 births and 4,080 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 27 deaths annually in every 1,000 persons living. The annual death-rate was 26 per 1,000 in London, 24 per 1,000 in Edinburgh, 26 in Glasgow, and 27 in Dublin. The annual rates of mortality per 1,000 during the same period

in the other large towns were—Brighton 14, Sunderland 19, Plymouth 22, Norwich 24, Nottingham 27, Bradford 34, Hull 23, Leicester 20, Bristol 24, Portsmouth 19, Sheffield 25, Birmingham 26, Wolverhampton 19, Leeds 25, Newcastle-on-Tyne 29, Oldham 29, Liverpool 31, Manchester 34, and Salford 30. The annual death-rate from the seven principal zymotic diseases averaged 3·7 per 1000 in these towns, and ranged from 0·5 and 0 7 in Brighton and Wolverhampton, to 5·7 and 6·0 in Liverpool and Bradford. The fatal cases of scarlet fever were again numerous in Bradford and Bristol, and 7 more deaths were referred to small-pox in Manchester and Salford, exclusive of 4 which occurred in the Monsall Hospital. In London the 1,771 deaths included one from scarlet fever, 22 from different forms of fever, and 21 from diarrhœa. Whooping-cough was particularly fatal last week, the deaths being 109, exceeding by 38 the corrected average number in the corresponding week of the last ten years. The 48 deaths from scarlet fever were below the number returned in any week since May last. The 22 deaths referred to fever were 19 below the corrected average weekly number, and included one certified as typhus, 15 as enteric or typhoid, and 6 as simple continued fever.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. Dolan Halifax.—Received: will appear in an early number.

Prof. Flower will continue his course of lectures at the Royal College of Surgeons of England "On the Relation of Extinct to Existing Mammalia" this afternoon and on Friday next, at 4 p.m.

Dr. W. H. Day will read a paper at the Harveian Society on Thursday evening "On Tuberculosis in Children, and the conditions which resemble it."

Dr. Thin will communicate his views of "The Formation of New Blood-vessels" to the Medical Microscopical Society on Friday evening next.

Physiologist.—You will find the subject ably referred to in *Land and Water* of January 19th.

A Country Doctor.—The article appeared in the *World* newspaper last week.

Pyrosis, or Water-brash.—A correspondent writes us that he has a most troublesome case under treatment, which up to the present has defied every remedy. He solicits the experience of his fellow-practitioners through the columns of the Medical Press and Circular.

Dr. Byrd, Illinois.—Mr. Rivington's "Lectures on Anatomy" will be continued in this journal shortly.

Births.

Beatty.—On the 10th inst., at 62 Lower Mount Street, Dublin, the wife of Dr. J. Guinness Beatty, of a son.

Lichtenberg.—On the 10th inst., at 47 Finsbury Square, London, the wife of Geo. Lichtenberg, M.D., of a son.

Tate.—On the 8th inst., at the Royal Barracks, Dublin, the wife of R. Tate, M.D., Surgeon-Major 2nd Queen's Royal Regiment, of a daughter.

Marriages.

Furse—Hosegood.—On the 10th inst., at the Parish Church, Thelbridge, South Molton, Devon, Edwin Furse, M.R.C.S., to Betsy Spencer, only daughter of the Rev. Samuel Hosegood, rector of Thelbridge, N. Devon.

McCarthy—O'Reilly.—On the 8th inst., at St. John's Cathedral, Limerick, John P. McCarthy, M.D., Abbeyfeale, co. Limerick, to Mary Cristina, eldest daughter of the late Dr. Philip O'Reilly, same place.

Deaths.

Bennett.—On the 1st Feb., at Huntington, Yorkshire, James Bennett, Surgeon, aged 84.

Budd.—On the 4th Feb., at Worcester, Herbert Walker Budd, F.R.C.S.E., aged 62.

King.—On the 4th Feb., at King Edward Road, Hackney, Wm. Grimwood King, L.R.C.P.Ed., aged 72.

Mitchell.—On the 5th Feb., at Clapham Road, Joseph Thos. Mitchell, F.R.C.S.E., aged 77.

Taylor.—On the 8th Feb., at 15 St. James's Terrace, Regent's Park, N.W., Caroline, the wife of Dr. Alfred Swaine Taylor, F.R.S., aged 66.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.

5 Henrietta Street, Covent Garden, W.C.

A. EBSWORTH, F.R.C.S., Director.

SURGICAL SOCIETY OF IRELAND.—The next meeting of the Society for the present Session will take place on FRIDAY evening next, the 18th day of February, 1876. Chair will be taken at half-past eight o'clock, precisely.

By Order,
B. WILLS RICHARDSON, F.R.C.S.I., }
JOLLIFFE TUFNELL, F.R.C.S.I., } Hon. Secs.

Royal College of Surgeons, January, 1876.

TO SURGEON-DENTISTS.—TO BE LET, a First-class HOUSE, in the best part of DUBLIN, in which a large PRACTICE has been carried on for the last forty years, and until the last few days. For particulars address A. B., Dublin Office of this Journal, 23 Ely Place.

A VACANCY has occurred in the office of PHYSICIAN to the North London Consumption Hospital, London and Hampstead, by the resignation of Dr. W. Lomas. Candidates (who must be Members or Fellows of the College of Physicians, and Graduates in Medicine of a University) are requested to send their testimonials to the SECRETARY, on or before 1st March.

Office, 216 Tottenham Court Road, W.

LISNASKEA UNION.

BROOKEBOROUGH DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—In consequence of the lamented death of their Medical Officer, Dr. Wilson, the Committee of Management of the above Dispensary District will, at their Meeting to be held on TUESDAY, 21st MARCH, 18 6, at the hour of 12 o'Clock noon, proceed to elect a duly-qualified Medical and Sanitary Officer for the District, at a salary of £115 per annum as Medical Officer, and £15 per annum as Sanitary Officer, together with fees for Registration and Vaccination.

Applications for the Office, with Diplomas and Testimonials, will be received by the Assistant Honorary Secretary, "James Sproul, Esq., Skeage, Brookeborough"

Personal attendance of Candidates will be required on the day of Election.—By order,

J. O'R. HOEY, Clerk of Union.

25th January, 1876.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c., can be had at the office,

40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

ROTUNDA LYING-IN HOSPITAL, DUBLIN.

Master:
LOMBE ATTHILL, M.D.

Assistant-Physicians:
ARTHUR V. MACAN, M.B. RICHARD D. PUREFOY, M.B.

This Hospital (the largest Chartered Clinical School of Midwifery in the British dominions) contains Wards for the treatment of Diseases of Females, in addition to the Wards appropriated to Lying-in cases.

A large Dispensary for the Diseases peculiar to Women is connected with the Hospital.

Clinical Instruction in Midwifery and the Diseases of Women is given daily.

The pupils are privileged to attend the Cow-Pock Institution, Sackville Street and York Street.

The Lectures are recognised by the Royal College of Surgeons in Ireland, London, and Edinburgh; the King and Queen's College of Physicians; the Apothecaries' Hall of Dublin and of London; the Army and Navy Medical Boards; and all other Licensing Bodies.

The Diploma from this Hospital is recognised by the Poor-law Commissioners as a qualification in Midwifery for all Hospitals and Dispensaries under their control in Ireland.

Accommodation is provided for a limited number of Intern Pupils.

Pupils can enter at any time.

Applications to be made to Master or Assistant-Physicians, at the Hospital, Rutland Square.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

A 39. Surgeon's Retail with scope for almost unlimited private practice. The death of the Incumbent has caused a great falling off in the receipts, but cash is at present taken amounting to about £11 a month. The house contains 7 rooms, with private door. Rent, £32. A personal introduction can be given to about 50 respectable patients, and it is believed that an income of £300 a year could be at once secured. Premium £100.

A 38. DEATH VACANCY. Receipts, over £700 a year. Appointments, £400. Great scope for increase. The practice is situate near a manufacturing town. The house with good stabling and land is held at a low rent. An efficient locum tenens prohibited from practice is in charge.

A 37. On the banks of the Severn an Unopposed Practice of a good class, realising £500 a year, including appointments bringing in £140. The house is convenient, close to a railway station, with stabling, orchard, &c. Rent, £42. An efficient introduction can be given.

A 36. NORTH OF ENGLAND. Transferable Practice realising £800 a year. Appointments, £350. Population about 5000; only 2 opponents. One horse sufficient. 12-roomed house, with stabling, &c., which can be let or sold, being the property of the Incumbent. Part of the premium may be paid by instalments properly secured.

A 34. Old established General Family Practice in a market town in YORKSHIRE. Population of the district, 8000. Receipts, £500 with appointments. Declining health the cause of retirement. Residence contains 12 rooms, surgery, and consulting-room, with garden, stabling, &c. Rent, £27. Premium, £400, of which the greater part may be paid by instalments. Furniture, &c., at valuation if desired.

A 33. In consequence of serious illness it is necessary to secure a suitable Successor to a FAMILY PRACTICE in a pleasant district of the Home Counties. The connection has been held by Vendor 11 years, and can be greatly increased. There are 3 resident medical men to a population of 8000. Receipts about £550 a year, including transferable appointments producing £330. These can be practically guaranteed. Convenient house with 13 rooms, stabling, &c. A thoroughly efficient introduction can be given. No gentleman without £150 at immediate command need apply.

A 31. MIDLAND. In a picturesque agricultural district. Receipts, £500 a year. Appointments, £80. One horse does the work. Patients good middle class. House well situate, containing 11 rooms, with stabling, garden, &c. Rent, £40. The Incumbent having the opportunity of entering upon Town Practice desires to make an immediate arrangement, but will give 6 months' active introduction. Premium, £350.

IRISH POOR-LAW INTELLIGENCE.

ATHY UNION.

A NEW ITEM OF EXPENDITURE.

Dr. O'Neill said there was one other matter that he would trouble the board with before leaving. A practice existed in the house which had now assumed such proportions that he felt it his duty to bring it before the guardians, with a view of their suggesting some remedy. The inmates of the body of the hall were in the habit of coming to him whenever he was in the house, and complaining of coughs and colds, and he was obliged to give cough mixtures ; the medicine thus supplied he was almost certain was never taken, and the bottles were never returned. The only conclusion he could come to was that the object of coming for the medicine was that the bottles might be concealed until there was an opportunity of taking them out of the house for the purpose of disposing of them. He was of opinion he was under the mark when he stated that from £25 to £30 worth of bottles were made away with in some way since he came to the house.

The master having been sent for and the matter explained to him by the chairman, he was asked if he could suggest a remedy.

Master—There appears to me a great difficulty in the way of remedying the evil, for these people can keep the medicine as long as they like. If I go to them and demand the bottles they have only to say that they are not done with the medicine yet, and I of course have no power to take them from them.

Dr. O'Neill—That of course is a fact.

Mr. Walsh said that if the master put his shoulder to the wheel he might devise some means of checking this evil, for it was no joke to have £25 or £30 worth of bottles made away with.

It was ordered that the master should take down the names of those supplied with bottles from the doctor's book, and that he use his best endeavours to see that they are returned.

COURT OF QUEEN'S BENCH—Jan. 29.

(Before Mr. Justice Fitzgerald.)

CERTIORARI.

In re the Queen's County Infirmary.

Mr. Walker, Q.C., on the part of Mr. Roe, one of the governors of the Queen's County Infirmary, and a cess-payer, moved for a writ of *certiorari*, to bring up two orders which had been made by the governors of that infirmary, for the purpose of having them quashed, on the ground that they had granted illegal payments of salary to the surgeon of that institution. By the 85th and 86th sections of the Grand Jury Act, the grand jury were empowered to present each half year a sum not exceeding £700, for the benefit of the infirmary, and to present each half year a sum of £47 for the salary of the surgeon. There was no question as to that item. The governors of infirmaries were constituted corporations under the 5th George III., chapter 20. Under the 6th section of the 54th George III, chapter 62, it was made lawful for the governors of an infirmary to pay out of the funds under their control a sum not exceeding £30 Irish a year, for the salary of an apothecary ; competent to compound medicines. This sum was paid tothe surgeon of the infirmary in question as if he were an apothecary,and also a further salary of £92 6s. 2d. The object of the *certiorari* was to take the opinion of the court as to the legality of these two last payments, for which the learned counsel stated that he had been unable to find any warrant.

Mr. Justice Fitzgerald granted a conditional order.

A.B. inquires—Can the magistrates in the case of a dangerous lunatic call to their assistance any medical man—say a workhouse medical officer—to examine and certify to the lunatic, thereby ignoring the dispensary medical officer ? I, as dispensary medical officer, have been obliged up to the present to certify without fee or reward. A case has occurred lately where the magistrates called to their assistance the workhouse medical officer and certified to him for £2 under the amendment to the Act (Section 14). On a former occasion they sent me into the workhouse under Section 10 of the Act, which compelled me to certify without fee or reward. Has the Act been repealed ? Does an amendment repeal an Act ? What redress have I to get, if any, and how, or where ? I fear a repetition of the same course should a case occur, unless some legal proceedings be taken to prevent it, if the Act be not in accordance with the statute.

Reply.—In our opinion the guardians have no power to pay anyone except a dispensary medical officer for certifying a dangerous lunatic. The Act 30 and 31 Vict. cap. 118, sec. 10 (see I. M. D., page 460) provides that—

10. Whenever any person shall be brought before any two justices and it shall be proved to their satisfaction that such person was discovered and apprehended under circumstances denoting a derangement of mind, and a purpose of committing some crime, for which if committed, such person would be liable to be indicted, the said justices shall call to their assistance the medical officer, or, if there be more than one, *the nearest available medical officer of the dispensary district in which they shall be at the time, and if there shall not be any such medical officer available, then the nearest available medical officer of any neighbouring dispensary district,* who shall examine such person without fee or reward.

The Act of last year does not repeal this clause, but simply adds to the foregoing clause, and amends it as follows :—

14. Notwithstanding anything in 30 and 31 Vict., cap. 118, sec. 10, it shall be lawful for any two justices causing any person to be examined *by any medical officer as therein mentioned,* if they think fit so to do, to make an order under their hands and seals upon the guardians of the union to which such person belongs, for the reasonable remuneration to such medical officer and for the payment of all other reasonable expenses in or about the examination of such person, not exceeding in the whole the sum of two pounds.

With reference to our correspondent's other queries :—

1. The Act has not been repealed.

2. An amendment does not repeal an Act unless the repeal of the clause is specifically stated.
3. Dr. M'Craith's redress is to call the attention of the Local Government Board to the matter, and the auditor will probably disallow the fee paid to medical officer who certified. It is a question whether this informality would not invalidate the certificate and render it necessary to get another, in which case Dr. M'Craith would get his fee for the new one. A letter to the Inspectors of Lunatic Asylums at the Castle would raise this question. The Inspectors could only entertain the question of legality of certificate, and the Local Government Board only the question of disallowing the fee.

Since the foregoing reply was penned our attention has been attracted to the following reply of the Local Government Board to the same question communicated to the Boyle Guardians at their last meeting :—

Local Government Board,
Dublin, 31st January, 1876.

SIR,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 21st instant, in which you request to be informed whether the medical officer of workhouses come under the provisions of section 14 of the Lunatic Asylum Act, 1875, in regard to remuneration for their services in the examination of workhouse inmates alleged to be lunatics, if the justices should make an order upon the guardians of the union for their remuneration, and in reply the Local Government Board have to state that there is not apparently any reference to the medical officers of workhouses either in the Act of last year (38 and 39 Vict. cap. 67, section 14) or in the 10th section of the Act 30 and 31 Vict. cap. 118 therein referred to. But the Local Government Board do not undertake to explain their opinion on the subject in the anticipation of a possible decision of the justices,

By order of the Board,
B. BANKS, Secretary.

It will be observed that the Local Government Board concur in the view which we have expressed above, but naturally decline to take the legal decision of the question out of the hands of the magistrates. Although we fail to see why a workhouse medical officer should be disentitled to certify a dangerous lunatic, if his attendance can be had as readily as that of the dispensary officer, yet it is obviously the law that he is so. Probably the dispensary surgeon was selected by the authors of the Act because he is more likely to be at hand when required.—ED.

RED TICKETS.

TO THE EDITOR.

SIR,—Your columns have often and ably advocated the cause of the Irish dispensary doctor. In the manly and fearless language which characterises your pages you have denounced the persecution to which the Poor-law officer is often subject by the unnecessary issue of red tickets. You have several times shown that in no way can an enemy of the doctor so successfully assail him, and that the parish doctor has no way of defending himself except by submission. Well does the assailed know that he has no redress. He may be engaged at another case : he is immediately pounced upon by his enemy for non-attendance. He attends as often as he thinks requisite : he is brought up on the charge of neglect. I do not for a moment say that dispensary doctors are not sometimes at fault, nay, I admit they often *are at fault*, but I think that no man, professional or lay, can read the accounts of the proceedings of some dispensary committees recorded in your Supplement without acknowledging that private quarrel and private spite are often at work, and that the doctor is often sacrificed, not to the public good, but to private enmity. I propose to show some of the causes of abuse in the issue of red tickets, the impossibility often of obtaining redress, and lastly, as far as I can judge, the remedy for the evil.

Before I enter into the causes of abuse, I think it necessary to inquire into the meaning of the word *pauper*. In the original acceptation of the term it meant a person absolutely destitute of means, or incapacitated by old age, infirmity, or illness, from supporting himself. By degrees it was *justly* extended to the artisan who was incapacitated by illness from earning it might be good wages. It has now come to include small farmers and persons of both sexes who have saved or inherited money, head artisans in small towns, and such like, who were at first never intended to be the recipients of Poor-law relief. The repeal of the Quarter Acre Section paved the way for many abuses, for though it expressly enacts that such a person is to be relieved in the *workhouse only*, still the latter part of the section is forgotten or overlooked, and the fact is only remembered that any poor farmer (for no limit is put to the amount of land he holds) may be relieved, and in my experience, and in my district, it has come to include farmers holding 6 and 8 acres.

Now Sir, I come to the causes of abuse of red tickets. The *pons et origo malorum* lies, of course, with those who issue them. I think I may divide the persons authorised to issue red tickets (excluding clergy of both denominations) into three classes :—

1. The nobility and gentry.
2. The farmers and shopkeepers.
3. The relieving officers.

As far as my experience goes, Class No. 1 err only in issuing tickets for their servants, stewards, gardeners, &c.

When we look into the subject, can anything be more unfair, or at variance with the object of the Poor Law, than to issue tickets for such persons? Let us take the case of a cook in a gentleman's family of fair means. She receives say £20 yearly ; she has house-rent free ; her living costs at a moderate computation £30 per annum ; *i. e.*, she has the equivalent of £50 a year and free lodgings. How unfair to charge her on the Poor Laws, and tax the ratepayers with the price of her medicines! Besides, it is contrary to the laws, for a master is bound to give medical attendance and afford medicine to his servants. The master can afterwards deduct the expenses from the servant's wages. Surely the British law cannot contradict itself, by laying down the rule in one place that masters are liable for the medical attendance of their servants, and in another place enact that servants are fit subjects for out-door relief and gratuitous medical attendance. As for classing stewards with paupers, it is ridiculous on the very face of it, for they are often paid more than the medical officer who is obliged to attend them.

We now, Sir, come to Class No. 2. I unhesitatingly state that the farmers are the prime offenders. Not so much the guardians (though they are bad enough) as the wardens, who are usually farmers and shopkeepers. The wardens are often of inferior grade, irresponsible (virtually) to any one. They have no fear of the censures of the chairman or their fellow-guardians before their eyes. What do they care about dismissal ? They are not elected by the votes of the people. They have to maintain no respectability before the eyes of fellow-committee men ; and even if their red ticket work is taken away from them it involves no disgrace. The guardians are to blame in their indiscriminate appointments. Every new guardian asks for a couple of the men who voted for him to be put on the list of wardens, and the result is that the number sometimess swell to the extent they have done in my district, where there are six men authorised to issue red tickets, in a circle the diameter of which is two miles or thereabouts. When small shopkeepers are appointed the evil is still worse. Such men often seek the appointment for the *prestige* it gives them ; and it is hardly to be expected that they will often refuse a ticket to a good customer because he happens not to be deserving of it, especially when the opposition shop of the village sells

groceries, spirits, and beer, and also has the power of giving red tickets.

The relieving officer forms the third of the trio into which I have divided red ticket givers. As they are the last, so are they the least liable to offend, for the reason that they are the only men who can be properly checked in the issue of visiting tickets. They are liable to be dismissed for giving tickets to persons not deserving of them. Still they do err, and sometimes grievously. For instance, I myself got a ticket from a relieving officer to visit the child of a farmer who possessed 20 acres of land. Moreover, the relieving officers are a very inferior class of men. They are not paid well enough—£25 to £30 per annum is not sufficient remuneration to induce a respectable man to accept the post. Hence the guardians often get a man who is utterly unfit for the post—drunken idle, and useless. But is will be urged you have your remedy—get the ticket cancelled. *Cui bono?* Certainly not to the dispensary doctors. In the first place, dispensary committees meet sometimes fortnightly, sometimes monthly, sometimes only on the day appointed for the re-election of the individual members. Let us take a case where they meet every fourteen days. The committee meets, say on the 1st of February: on the 2nd the doctor gets a ticket to visit a farmer's wife in labour; he goes, as in duty bound, and by the time the committee meet again the woman is up and nearly well. What redress has he to get the ticket cancelled—what then? He cannot claim a fee, even if such be the case, and he has *the solid satisfaction* of having the ticket cancelled, and knows hereby that it was no fit case; and that he had given his skill and time for nothing where the husband was able to pay!

In black tickets the abuse is still more glaring. Many is the time I have treated cases knowing them to be the children of farmers, brought by poor persons—skin diseases, worms, &c., are almost always treated at the dispensary. I need not say they are as deserving of a fee as a pleuriy or a fever. But the man who would look to have a black ticket cancelled must be very foolish indeed, for he would be looked upon as cantankerous and quarrelsome, and he would find the committee he had summoned from their hunting, farming, and shopkeeping very unwilling to cancel a ticket which in their eyes gave the doctor no further trouble than a few words, or the compounding of some medicine.

I have mentioned some of the evils and their causes; now for a few words as to the proposed remedies.

Imprimis, the more careful definition of the term *pauper*—the clear statement by the Local Government Board that none are to receive Poor-law aid except those who *are destitute*. The clear understanding that none who are receiving more than so much a week are to be relieved. The recognition of the unfitness of master shoemakers, tailors, &c., who employ hands. This would exclude tradesmen in small towns and villages who employ sometimes as many as six hands, yet who get ticket when ill on the plea that they are unable to work.

2. The total repeal of the order which allows small farmers at the discretion of the issuer to receive red tickets. It is a very poor farmer who cannot afford some small fee to a medical man; he always has fowl, &c., to nourish him, and it is very unfair to allow such men to add to the taxes by receiving out-door relief if they are unable to be removed to hospital.

3. Strict exclusion from the benefit of the Act of the servants of men who pay a certain amount of poor-rates; or, better still, an exclusion of servants, outdoor or indoor who receive a certain amount of wages.

4. The more careful appointment of wardens, and the limitation of their number. It is monstrous to have 12 or 15 wardens in a district. The best check would be to have such men appointed by the majority of votes of the committee, who, as local men best know their character, rather than by the board, who are often influenced by the recommendation of an individual member.

5. A strict clause against the appointment of publicans shopkeepers, &c., as wardens. It is too much, as I before, to expect such men not to be influenced by e r customers.

6. The appointment universally of the parish priest and his curates as wardens, and of the protestant or Presbyterian clergy and their curates; such menare the best judges of those deserving aid, and besides could save many a life. Some men are of opinion that clergy of all denominations are not fit persons to have as red ticket issuers. I can see no ground for such reasoning; on the contrary priests and clergymen from their frequent contact with death and disease, are generally very fair judges of bad cases, and could send for the doctor often at times when no other ticket giver could be got at.

7. The appointment of responsible persons with respectable salaries as relieving officers. Who can expect to get a really good man for £27, or even, where he has much to do, £40 per annum? I think that two men with £80 salaries, and fees as subsanitary officers, would do more efficient work than three men at £27 or £30, and one man at £40. The two men at £80 salaries and sanitary officers' fees could keep some sort of conveyance, and do twice the work of four men jaded by long journeys on foot and halft starved into the bargain. Such men would be above taking bribes in the shape of drink, and would save the ratepayers a round sum in the year in medicines, outdoor relief, &c.

Lrstly. What remedy has the doctor in the event of a ticket being cancelled? None that I know of. The only way that I can see of preventing such tickets being issued is the immediate dismissal of the issuer by the Local Government Board on receipt of the red ticket and the minutes of the committee cancelling it. Or the liability of the issuer to pay the doctor his fee on the ticket being cancelled, in default of which his dismissal under sealed order.

I have been, I am afraid, rather prolix, but, Sir, I feel that the dispensary doctors require some protection not now afforded them, and the ratepayers some such changes to prevent the already high rates from rising still higher.

I am, Sir, yours, &c.,

A Dispensary Doctor.

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING FEB. 5, 1876.

Total registered deaths in Dublin and suburbs *	...	163
Ten years average of same week	...	202
Decrease of mortality below average	...	39
Ratio of deaths, suburb of Rathmines ...	30	per 1,000
" " " Donnybrook †	26	"
" " " Blackrock ...	14	"
" " " Kingstown ...	14	"
" " Entire Dublin district ...	27	"
Comparative Ratios—London	26	"
" " Glasgow... ...	26	"
" " Edinburgh ...	24	"

* District extends over 10,050 acres, and contains 314,666 persons.

† Th strict includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week, was 24, viz., 2 from fever (1 typhus and 1 typhoid), 8 from whooping-cough, 4 from measles, 3 each from scarlet fever and croup, 1 each from erysipelas, diarrhœa, &c.

Seventeen children died from convulsions.

Bronchitis caused 33 deaths (against an average of 41 for the fifth week of the years 1866-75), and pneumonia 4.

Three deaths were ascribed to paralysis, one each to apoplexy and insanity, and 2 each to epilepsy and brain disease unspecified.

Phthisis caused 16 deaths, mesenteric disease and 5, hydrocephalus, or water on the brain, 3.

ELECTION OF MEDICAL OFFICER FOR BAGENALSTOWN DISTRICT.

A MEETING of the committee of the Bagenalstown Dispensary was held for the purpose of appointing a successor to Dr. Trayer, recently retired owing to ill health. Of the several candidates for the appointment, Dr. Charles Scott, who had been acting as *locum tenens*, was all but unanimously elected.

NORTH DUBLIN UNION.

A LETTER was received from the Local Government Board, informing the board that they had received from Drs. Nolan and Ferguson return forms relating to No. 1 North City Dispensary District, in which the medical officers refer to the large and increasing number of visiting tickets presented to them. The total number of visiting tickets received in No. 1 district during the year 1875 was 4,562, as compared with 4,098 in the year 1874. The number of cases in each of the districts Nos. 2 and 3 during the quarter referred to was considerably less than the number in district No. 1, and with reference to the former correspondence which has taken place on the subject, the board request that the guardians would have the goodness to take the matter again into their consideration.

Dr. Nolan stated that during the last three months the visiting of external patients had been very heavy, and on January 3rd, 1876, he had 20 new visiting tickets presented to him for his part of the district alone.

The matter was referred to the dispensary committee for consideration after some conversation.

Ephemerides Medicales.

UNDER this heading some interesting notes appear in *l'Union Médicale*. Amongst them are the following:—

"On the 15th June, 1784, 'le R. P. Gerrard,' Superior of the Order of Charity of Rochelle, announces that he has worked in that town a miracle with animal magnetism: A poor devil of a soldier, dropsical from head to foot, suffering agony, and almost moribund, on being submitted to some simple passes, commenced to urinate abundantly, and to go to stool. He was cured. 'This cure,' adds le P. Gerrard, 'has drawn to me so many patients that I am obliged to shut myself up.'"

"On the 17th June, 1644, Anne of Montagré, wife of Charles of Bourbon, Duke of Soissons, died. The Faculty of Medicine in Paris attributed her death to an emetic given by Vautier and De Zorme, 'médecins étrangers' at the School of Paris."

In the *Union Médicale* two cases are noted by Dr. A. Mattel of children born with teeth; in the cases noted those present were the central incisors of the lower jaw. In his comments upon the occurrence he takes note of the popular superstition that such children are the offspring of peculiarly healthy and vigorous parents, and makes mention of the fact that such was not the case in the instances that came under his notice.

LECTURES ON DISEASES OF THE EAR.

By Geo. P. Field, M.R.C.S.,

Aural Surgeon, and Lecturer on Aural Surgery at St. Mary's Hospital.

Gentlemen,—We now come to some of the more severe forms of chronic aural catarrh. In my last lecture I endeavoured to point out the great benefit derived from the use of Politzer's air-bag in the milder forms of this disease, and to-day I shall take cases of a more serious character, where the use of the Eustachian catheter is necessary.

Not only in severe cases of chronic aural catarrh, however, is this instrument of the greatest service—but occasionally we meet with patients with impervious Eustachian tubes (and deafness more or less will continue as long as they remain closed), where Politzer's process fails altogether to overcome the obstruction, but where, on the other hand, immediate relief is afforded by passing the Eustachian catheter. When the tube is again pervious, air is admitted into the tympanic cavity, and at the same time any abnormal secretion that may have been pent up by the complete closure is allowed to escape. If mucus, pus, &c., be permitted to remain undisturbed in the tympanum, you can easily understand what vicious results are likely to take place, eventually leading to permanent deafness.

You see, then, how important it is to be able to pass the Eustachian catheter, and it is remarkable how few medical men are able to do so satisfactorily. By far the easiest and best way of learning to use this instument is, I believe to pass it in the manner first suggested by Dr. Löwenberg. He recommended that the instrument, after it had reached the pharynx, should be turned inwards (instead of outwards) till it hooked itself behind the vomer, and as it could then be withdrawn no further, to turn it completely round at right angles and the point of the catheter would be placed in the exact position sought for—viz., in the mouth of the Eustachian tube.

If the instrument, after reaching the pharynx, is withdrawn in the ordinary way, with the point turned outwards until the orifice of the Eustachian tube is found, great difficulty is frequently experienced. The instrument is not withdrawn far enough (or may be too far), or perhaps the point is inserted into the fossa situated behind the Eustachian tube.

You must remember also that the mucous membrane in nearly all catheter cases is in a delicate state, oftentimes highly sensitive, so you can imagine that constantly moving the instrument backwards and forwards adds considerably to your difficulty.

Warm the catheter in hot water and introduce it into the inferior meatus of the nose (and this is best done by depressing the patient's lip), pass it along the floor of the nares until it reaches the posterior wall of the pharynx, taking care to keep the instrument at right angles with the plane of the face, withdraw it until the septum nasi is felt; if it is then rotated with the point downwards to the opposite side—that is, turn it outwards and a little upwards (and this position will be shown by the ring at the other end of the catheter), the mouth of the Eustachian tube will be easily found.

I have passed the Eustachian catheter several thousands of times in this manner with the greatest ease. I am confident it is by far the better plan, for in the out-patient department I have taught gentlemen readily enough in this way; whereas by the other mode they always experience difficulty in learning. I should not forget to mention that the patient should be placed facing the light, in a chair with a high back, against which the head can be firmly rested. The Eustachian catheter should never be passed on young children—it is unnecessary, very difficult, and moreover dangerous, for you can never by any means induce them to keep still. I very rarely use it for any patient under 15 years of age.

What are the difficulties and dangers that arise from the introduction of this instrument?

Excessive narrowness of the nasal fossa. Extreme sensibility of the pituitary membrane, and the pain produced by the least touch. From using a too large or too curved an instrument, or giving it a wrong direction, are some of the difficulties given by M. Triquet, and the accidents arising from the operation he divides into local and general.

The local accidents are :—

1. Laceration of the inferior part of the nasal canal: it causes only slight pain and one or two drops of blood.

2. Extraordinary sensibility of the pituitary membrane, which may bring on sneezing, or may render the contact of the catheter very painful.

3. Excessive lachrymation.

4. A few drops of blood often flow during the operation, probably from the Schneiderian membrane being lacerated, or in some subjects where the mucous membrane is red and inflated the simple contact of the instrument may give rise to a true epistaxis, which may always be promptly arrested by the inspiration of a little cold water.

5. Nervous cough.

6. As a result of simple or granular chronic pharyngitis the tonsils may have remained hypertrophied, and it is not uncommon to meet with a spasmodic contraction of the pavilion of the Eustachian tube, when the catheter is about to enter the orifice. In nervous subjects, as soon as the catheter touches the pituitary membrane, the velum palati is convulsively drawn upwards. During these violent contractions, whatever be the cause, the peristaphyline muscles, inserted near the mouth of the Eustachian tube, completely effuse the opening, so that an instrument cannot pass it without effort.

7. If the surgeon employ too much force to overcome the contraction of the muscles, the mucous membrane may be torn, so as to give rise to the production of emphysema at the first attempt at deglutition or at inspiration. The symptoms resemble œdema of the glottis in its last stage. On forcibly drawing down the tongue with the finger, there is perceived to be considerable emphysema, raising the whole of the mucous membrane of the pharynx, and even invading the larynx, especially the arytæno-epiglottic folds. It is requisite only to tear with the nail of the finger which holds down the tongue one of the emphysematous projections of the mucous membrane—the air escapes and the patient recovers.

8. Rupture of the membrana tympani.

The general accidents are : Rigors and fever ; facial neuralgia ; obstinate headache ; and an increase of the deafness, &c. Suspension of the treatment is generally sufficient to arrest these accidents.

Having now given you what I consider the best means of passing the Eustachian catheter, and some of the difficulties that may be met with in the operation, I pass on to the various forms of Chronic Aural Catarrh where the use of this instrument is appropriate. We will, however, first begin with a case of obstruction of the Eustachian tube, on which we are unable to make any impression by Valsalva's or Politzer's process, but which yields readily enough to the catheter. It is well to remember that where you meet with patients whose hearing varies from time to time, we may be almost certain that the mischief is to be found in the Eustachian tube and not in the tympanum. The congested state of the mucous membrane of the tubes being increased (especially in damp weather), extra secretion is poured out, and the mucous surfaces meet and thus exclude the air.

A. D., æt. 69, has been deaf four months. Came on first from taking cold from sitting at an open window. Both tubes closed. Politzer's process of no effect. Cannot hear watch on contact right ear. Hears one inch left. Catheter passed, and repeated twice a week for three weeks. She rapidly recovered her hearing, and the last time I saw her says "she can hear as well as ever."

J. F., a painter, æt. 40, had attended at St. Mary's for a great many years, formerly under Toynbee and Allen, and latterly under my care. His hearing varies from time to time, but suddenly, about every six months or so, he gets very deaf, and comes to the hospital to get relief from the catheter. The Politzer bag does not make the slightest impression on him, but directly the catheter is passed and the air-douche used, he says "he hears a bang," and his hearing comes back. He is ordered a strong astringent application for the throat (argenti nitratis, gr. x. to ℥i.) and he gets almost well again. He is able to keep the tubes open by Valsalva's process with comparative ease for some months, until damp or foggy weather again brings on a total obstruction of the tubes.

In these cases there is always great concavity of the tympanic membranes, the centre part especially being sunken inwards, and in the upper portion the short process of the malleus shows out like a pin's head.

I could repeat numerous cases of the same kind where the greatest benefit has been derived from the air-douche regularly used through the catheter.

More powerful remedies, however, are often necessary. Fluids or vapours can be blown in like manner through the Eustachian tubes.

Thus, as Von Tröltsch remarks, "In moist swelling, and where increased secretion of the mucous membrane is present, vapours of chloride of ammonium are most useful, best evolved in a nascent state, whilst in a dry and thickened condition of parts, tepid or warm water vapours, alone or with iodine, introduced with a certain degree of pressure into the tympanum, most speedily promote reabsorption. Injections of astringent or slightly stimulating fluids (solutions of zinc, iodine, &c.) often produce the same effect, and are preferable in the case of a narrow Eustachian tube, and when a too extensive irritation of the nasal mucous membrane would be produced by warm vapours.

A. G., æt. 64, came to the hospital March 31st, suffering from deafness, brought on from cold five years ago. Both tympanic membranes concave, and of dark yellow colour. Eustachian tubes completely closed. The Politzer bag was used without any benefit. Catheter passed. Moist sounds heard in tympanum. A solution of sulphate of zinc (gr. v. to ℥i.) was injected into the tympanic cavities regularly twice a week, and after every application the hearing distance improved. On April 14 says "she can now hear the ticking of her clock," which she has not heard before for five years. On June 2nd she left the hospital with very fair hearing power.

According to Politzer, if there is little or no increase in the hearing distance, after repeated employment of the air-douche, we may infer that the deafness is caused by the sequelæ of the catarrhal affection, viz., thickening of the mucous membrane and of the coverings of the ossicula, with rigidity and diminished mobility of them, we can only expect improvement from the use of moderately stimulating injections, together with the use of the air-douche. In this state of things I have found great benefit derived from an often-repeated injection of a solution of iodide of potassium (gr. x. to ℥i.). For example, in a lady (sent to consult me by Mr. Spencer Smith) who had been deaf for two years, the hearing improved very satisfactorily from this treatment. The tympanic membranes were of a very dark colour, and sunken inwards. Hearing distance, when I first saw her, was 12 inches right, 9 inches left. Feb. 28th : 12 right, 15 left. March 4th : 15 both. 9th : 16 right, 19 left. 16th : 19 both. April 1st : 18 right, 24 left. 15th : 20 right, 24 left. The hearing distance varied after this from time to time ; the best was 26 right, 25 left. In very deaf people, one inch gained makes a very considerable difference. In more recent cases the recovery from this mode of treatment is sometimes much more rapid, and where the benefit derived may be counted in feet instead of inches.

In some cases of a thickened condition of parts the injection of a weak solution of iodine is of the greatest service. Thus, in E. R., Esq., who came to consult me for his deafness. He heard my watch one inch in the right ear, but was unable to hear a sound in the left. He gradually improved by this means after everything else had

failed, and when I last saw him he heard 6 inches right, 4 inches left, and I hope to get still better results by further treatment. Weak solutions of sulphate of copper, liquor potassæ, nitrate of silver, hydrate of chloral, &c., &c., are often useful. Of course it is of the utmost importance to select your remedies suitable to the condition of the patient, to the state of things observable when looking at the membrana tympani, and to the diagnosis arrived at from the various sounds heard through the otoscope, or psophometer, as some prefer to call the diagnostic tube.

In the treatment of these cases of chronic aural catarrh it is, I consider, always best to begin with the air-douche, and see if any good result can be obtained, before we go on with the injection of fluids. I think very often this is neglected. A lady, a short time ago (the Hon. Mrs. C.), came to consult me for deafness. She said she had seen numerous aurists in France and Germany, and that they injected all kinds of fluids through the catheter, and instead of getting better she got worse. I treated her simply by the air-douche, and she regained her hearing in a remarkable way, and lost entirely the pain and noises in her head she had previously suffered from.

There are other cases, of course, of disease of long-standing where we fail altogether to make any impression by means of the Eustachian catheter. In some of these patients puncture of the membrana tympani is said to have proved of service.

Mr. Hinton thus describes the operation: "Whatever instrument is used, it should be introduced into the meatus through the speculum with a good light falling on the membrane, which should be punctured in its inferior portion, either in front of or behind the termination of the handle of the malleus. A small amount of bleeding follows the incision, and if the case be a favourable one, an immediate improvement of hearing occurs." He recommends a syringe fitting hermetically into the external meatus for washing out the cavity of the tympanum. Dried mucus which has collected behind the membrana tympani can by this means be forced out into the Eustachian tubes or pharynx. It is very difficult to keep open an aperture made in the membrana tympani; in most cases the puncture rapidly closes up, so that unless (before the closure) you have been able to get rid of some of the inspissated mucus little good has been done.

This operation should only be attempted where other less hazardous means have been previously employed without avail, and in such cases where we are quite certain that the deafness can be relieved by the removal of the abnormal secretion which is interfering with the proper function of the membrana tympani.

A gentleman came to consult me a short time ago with facial paralysis, together with almost total deafness on one side, which came on after this operation had been performed by a surgeon in the north of England. Another patient told me that he had had both membranes punctured by an aurist every week for a period of two months; he said "it always healed up the next day, and I am worse than I was before." Several deaths have been recorded from inflammation of the brain resulting from this operation. I agree with Allen when he says, "We must not attempt by the venturous operative surgery of laying open the tympanum to relieve the patient before we have exhausted every other possible means of treatment." We can, I am certain, do an immense amount of good in long-standing cases of chronic aural catarrh by the use of the Eustachian catheter and the injection of carefully selected fluids into the tympanum, together with constitutional treatment suitable to the case.

In conclusion, to use the words of the author I have just mentioned, "whenever you see a patient dull of hearing, vacant in look, and only when he listens attentively capable of entering into conversation and distinguishing what is said (that is only when he exercises the stapedius muscle by an effort of the will), it may confidently be assumed that the accommodating power of the ear is defective, or lost, in consequence of congestion and thickening of the lining membrane, plastic exudations, or adhesions in the cavity of the tympanum. The description of these symptoms and states of the middle ear, and of their liability to recurrence, will impress on your minds the necessity of preventing by timely treatment their becoming the source of permanent deafness."

TORSION OF ARTERIES. (a)

By Robert M'Donnell, M.D., F.R.S.
Surgeon to Dr. Steevens' Hospital, Dublin.

Mr. President and Gentlemen,—As the paper which I am about to communicate to the Society consists chiefly of a series of demonstrations as to the best mode of securing arteries by torsion, it is necessary for me not to make a written communication, as I should only have frequent interruptions in order to show the instruments, &c. It is unnecessary for me to enter at any length into the history of torsion. It is enough to remind this Society that in the year 1829 M. Amussat made his well-known communication on the subject to the Académie Royale de Médecine. The practice which he recommended was adopted by some of the leading French and German surgeons of the day (Boyer, Dupuytren, Velpeau, Lieber, Fricke, Shrader, &c.). British surgeons did not for some years take any notice of the subject. In 1834 Mr. W. B. Costello published a paper in the *Lancet*, "On the Torsion of Arteries for the purpose of arresting Hæmorrhage," but the practice was not followed. It was only a few years since, after Sir James Simpson had written extolling acupressure as a means of arresting hæmorrhage, that in a short note in the *Lancet* Professor Syme brought back the attention of the profession to the subject of torsion. It is probable, therefore, that the revival of this practice was really due to the rivalry existing between these two distinguished professors of Edinburgh. It is, however, unquestionably to the exertions of Mr. Thomas Bryant, of Guy's Hospital, and Professor Humphrey, of Cambridge, that torsion is now becoming an established practice. Since the appearance of Mr. Bryant's memoir on the subject in the "Medico-Chirurgical Transactions," 1868, it has been practised by my colleagues and myself in Dr. Steevens' Hospital, Dublin. We are, therefore, after so many years experience, entitled to speak with some authority on the subject. I quote, therefore, with great satisfaction the words of Mr. Colles, Regius Professor of Surgery in Trinity College, and Surgeon to the Queen, as expressing our joint experience: "For the last six or seven years," he says, writing on the subject in the *Irish Hospital Gazette*, "in Steevens' Hospital my colleagues and I have seldom resorted to any other means of arresting hæmorrhage even from the largest vessels, and we have never had reason to regret the adoption of the practice." Any one desirous of making himself expert in the art of arresting bleeding by torsion should begin by making a few experimental trials on vessels taken from the subject. One or two simple principles are thus learned. Suppose we take a few inches of the femoral or brachial artery cleanly dissected out from a recently dead subject, such as I have here. The end of the vessel is caught hold of by a pair of forceps (closing with a spring-catch or bolt) broad enough to catch the entire mouth of the vessel. By means of a second pair of forceps, such as these *(forceps exhibited)*, the vessel is seized at right angles. This second pair of forceps consists of two blades; a projecting ridge on one blade fits into an indentation on the other. Seized transversely in this second pair of forceps, the vessel is squeezed tightly, and thus its internal tunics are nipped across, while its outer coat, which is much tougher, is not. The second pair of forceps have now done all that is required of them, and the twisting is accomplished by the first pair, the vessel being overlaid and twisted at the point where the inner tunics have been nipped through.

(a) Communicated to the Surgical Society of Ireland, Feb. 4. The discussion will be found at page 157.

It is curious and indeed interesting to observe what happens as the twisting is continued. The inner tunics actually peel off and double up, becoming invaginated in the vessel; the external tunic twists into a firm cord with little or no tendency to untwist. The appearance of this invagination of the inner tunics is well represented by Mr. Bryant in the illustrations accompanying his paper already alluded to. It was, however, admirably figured long before by P. J. Manec in his works, "De la Ligature des Artères," 1832 (plate xi., figs. 2, 3, 4, and 5). A few trials, however, on the arteries of the dead subject, and a careful inspection of the result will do more than any illustration to satisfy the surgeon of the security which arises from the peculiar mode in which torsion obstructs the end of an artery. I would venture to assert that no surgeon who will take the trouble of investigating the matter by a few experiments of this kind will long resist the practice. It is obvious that torsion is not to be applied to all kinds of vessels in exactly the same manner. Experience teaches that we must adopt somewhat different expedients in securing by torsion vessels differing in size and position; the greater or less laxity of the tissue which surrounds the vessel, the character of its sheath, &c., all make it necessary to modify somewhat the mode of procedure. The surgeon should have at hand, therefore, several varieties of torsion forceps, since a pair well suited to twist one vessel may not answer so well for another. Perhaps the simplest and most practical mode in which I can hope to convey to those who have not as yet learnt the mode of torsion for themselves some idea of the details of the practice is by describing as accurately as I can how it may be done on different vessels. *First*, then, vessels met with in amputations of about the size of the radial or ulnar are easily secured. They are best twisted by the aid of toothed forceps, such as I have here. These forceps are, I believe, generally known as "Syme's torsion forceps." The vessel is to be seized right across its open mouth and drawn out a little; it is then caught just beyond the forceps, between the thumb and forefinger of the left hand, so that the nail of the thumb may give it a good pinch, and nip through the internal tunics; then twist and all is secure. The end may in the case of such vessels be twisted off or not, as the operator pleases. If the forceps catch the vessel by the lip only, or at the side, it will of course continue to bleed. In order to be successful the vessel must be caught entirely across the mouth, and the outer tunic must be twisted, as seen diagrammatically represented on the board. *Secondly*, if the vessel be surrounded by a large quantity of lax areolar tissue, as in the scrotum, prepuce, around the eyelids, or in the loose tissue forming the bed from which a fibrous tumour has been removed, the forceps last mentioned do not answer well. The teeth project too much. When twisted they catch in the loose areolar tissue, as a corkscrew would if twisted in tow; this prevents the proper twisting of the vessel itself at one point, viz., where the inner tunics are divided by being nipped. For vessels of this sort such forceps as are here (*forceps exhibited*) are very good. As before, the vessel is to be caught across the mouth, if possible, nipped by the nail of the thumb of the left hand, and twisted so that the external tunic is overlaid at the point where the nip has been made. *Thirdly*. Vessels lying in muscular tissue are sometimes troublesome to secure by twisting. This is not so when, as on the face of a stump, the vessel can be fairly and completely caught by the mouth. Here muscular branches of an artery are as readily secured as other vessels. But suppose, for example, that a breast has been removed, and the great pectoral exposed; a bleeding point on the muscle is seized and twisted; the part seized tears away readily and leaves a little pit bleeding more than before. The vessel has in truth been caught sideways and a piece torn out of it, all the more readily because the muscular tissue in which it is imbedded is friable. The difficulty in these cases arises from the fact that where we have to deal with a longitudinal and not a transverse section of a muscle there is more trouble in making sure that we catch the vessel right across the mouth. If it be scraped with the handle of a scalpel, perhaps, if need be, rather roughly, so as to let the vessel be distinctly seen, and caught, not longitudinally, but transversely across the mouth, the twisting maybe performed as readily as on any other vessel. *Fourthly*. Some special difficulty may be experienced in securing by torsion vessels which lie deeply between bones and in the close vicinity of a dense membrane,—as the interosseus arteries in the forearm and leg. In this case the vessel must be detached carefully, either by the handle of the scalpel or by dissection from its surroundings. Obviously if, in seizing such a vessel, the interosseous membrane is also taken hold of by the forceps, a successful twisting would be impossible. From this membrane the vessel must be entirely separated. *Fifthly*. Such vessels as the brachial, femoral, or popliteal, are in general very readily secured by torsion; in the great majority of instances it is only necessary to attend to the principles already laid down, viz.: 1st, to catch the vessel clean across the mouth; and 2nd, to divide by some means the inner tunics and twist the outer coat at that point. In all cases of amputation for injuries, where the tissue round the vessel is healthy, it is usually quite an easy matter so far to detach from the adjacent parts as to accomplish in a few seconds all that is necessary. If, however, we are amputating in the neighbourhood of diseased structures, sinuses, &c., where the parts are matted together, it is necessary by some touches of the point of a scalpel to free the vessel from the surrounding parts. Even then it cannot be drawn out as in the former case. The parts around are unyielding, and it is by no means easy to get space enough beyond the ends of the first or grasping forceps to apply the second or nipping forceps. Under these circumstances I adopt the following expedient. I place a silk ligature round the vessel immediately beyond the ends of the grasping forceps (which for large vessels are to be made big enough to catch the entire mouth of the artery). This ligature I pull home until it snaps across. To make sure of accomplishing this with some facility I have the silk fixed on wooden cylinders, so that it can without hurting one's fingers be pulled home until it snaps across. It invariably snaps at the knot, and is to be pulled off and cast aside. We thus accomplish, by a snapped ligature, what is done in other cases by the nipping forceps, and then proceed to twist; three or more half-turns are sufficient for the femoral, and I always in this case leave the end still adhering. If the wound is washed with chloride of zinc solution or otherwise properly antisepticized with carbolic acid water, &c., these portions do not act as foreign bodies, but are absorbed as Lister's catgut ligature is.

[Dr. M'Donnell then exhibited the brachial artery of a man who had died five days after an amputation of the arm, in which the brachial artery had been twisted. He said the vessel was perfectly secured, and that the extreme and which had not been twisted off showed no disposition to slough. This case was sufficient to prove that the objection raised as to torsion—that the extremity of the vessel was likely to slough and act as a foreign body—was groundless. There was in truth no more likelihood of this occurring after torsion than after the application of an ordinary ligature, as in this case also the extremity of the vessel had the same risk of sloughing.]

Dr. M'Donnell then proceeded:—The mode which I now propose, and which I have over and over again put in practice, of using a silk ligature, not too strong, pulled home until it breaks, for the purpose of dividing the inner tunics of the vessel previous to twisting, is very simple, and, I may add, very effectual. It supplies the place of the nipping forceps or the thumb-nail, and is applicable to vessels of all sizes which are unmanageable in other ways. In fact, no readier way of securing ordinary sized arteries can be suggested than to put on, first, a silk ligature, and then seize the knot in a pair of torsion forceps and twist it off; the vessel is perfectly secured, and there is no foreign body left behind in the wound. Large wounds are often then found healed on the twelfth to the fourteenth day; that is about the time that, in cases where a bundle of ligatures have been left in a wound, these are beginning

to separate. Some ingenious instruments have been devised for performing with a single instrument the double manœuvre of nipping the coats and grasping the vessel to twist it. Among these I would mention a kind of forceps invented by Dr. Addinell Hewson, surgeon to the Pennsylvania Hospital in Philadelphia. Dr. Hewson was good enough to present me with a pair of these forceps last year, when I had the pleasure of visiting his city. I have since then had several opportunities of using them, and found them do their work satisfactorily on vessels not surrounded with brawny, tough, infiltrated structure. Where, however, this condition exists, or, in fact, wherever there is any difficulty in drawing the vessels out a little from the surrounding structures, Dr. Hewson's forceps are open to the same objection as arises in attempting to use the cross-nipping forceps. There is not space enough to apply them, and to nip properly beyond the ends of the grasping forceps. The advantage of the ligature pulled until it snaps and comes away is simply that we can in this way accomplish all we wish to do as regards dividing the inner coats upon a very limited piece of the artery.

[Dr. M'Donnell also exhibited a pair of forceps devised by himself, and made by Messrs. Weiss and Co., of London, and designed also by a double manœuvre to nip through the inner coats and seize the mouth of the vessel so as to twist it; but he said he had not found the instrument successful in actual practice.]

It will be admitted that experience alone can give one confidence in this mode of arresting bleeding from large vessels. Practice can only make one expert in the performance of torsion. But it will, we feel confident, repay those who bear the first anxiety and take the trouble. There can be no more gratifying spectacle for a surgeon than to see a large wound (as after extirpation of a breast or amputation of a thigh) closed up without a single ligature remaining to interfere with primary union. Anæsthesia, torsion, and antiseptics, with catgut sutures, &c., seem to render almost perfect the healing of wounds after operations.

NERVOUS DIARRHŒA IN FEMALES. (a)

By Robert Lafayette Swan, F.R.C.S.,
Lecturer on Anatomy in Dr. Steevens' Hospital School.

I am desirous of bringing under notice a certain condition in which the rectum may be found, in the hope that information which may guide the practitioner in one of the most troublesome affections he is called upon to treat may be gained from some of the experienced surgeons present.

The condition to which I allude presents features both local and general which differ from those of ordinary anal fissure, usually readily amenable to treatment. On examining the part, the mucous membrane at its junction with the integument appears red and irritable, and small patches of excoriation are discovered. These occupy no definite situation, and are usually elongated in the axis of the intestine, at the posterior margin of the anus; one of these may present the ordinary appearance of an anal fissure, and may in the progress of the case be successfully treated by incision, without modifying the general state alluded to. This condition may or may not be associated with hæmorrhoids. The sphincter is usually tightly closed against the entrance of the finger, and the patient complains of considerable pain during and after its introduction. On withdrawing the finger it is found to be covered either by mucus or the contents of the bowels in a fluid state, but wholly unstained by blood or by any discharge resembling pus. After each examination a mucous discharge from the bowels or some fæces follows the finger or speculum through the sphincter and appears externally. The persons in whom I have observed this condition to exist were females between thirty and forty years of age, of indolent habits, and at the same time excitable temperament. On eliciting the subjective symptoms of each case, I found that a form of diarrhœa existed, to which the term nervous or emotional, in the absence of a better, might be applied. This we know under exceptional circumstances—such as great fear, or horror, is not an uncommon occurrence, even in health. It not unfrequently happens to the culprit as he is being prepared for the fatal drop; and history records that the great Dr. Johnson, under the influence of dread, met with a similar catastrophe. An exaggeration of this tendency can certainly exist, and trifling causes of anxiety which daily befall most people rendered for a time the existence of two individuals whom I have known wholly miserable by producing this diarrhœa at inconvenient periods. The persistency of this symptom led me to consider, might it not have an intimate influence on the condition of the anus? I concluded that it might be regarded in a great degree as the cause of the affection. In illustration, I shall briefly refer to two cases.

Mrs. R., aged 32, had been married several years, had one child, now nine years old. Had been suffering for the past two years from pain in the back and thighs, and soreness in the anal region. Received a shock some years ago, and states that she has since been extremely nervous, and any trifling fright has constantly produced diarrhœa, or a watery discharge from the rectum. She has had on many occasions to empty the bowels nine or ten times, in the morning especially, on the eve of any unusual undertaking. On my first interview this lady had to leave the room a couple of times for that purpose. After making a careful examination of the rectum by means of the speculum, no abnormal appearance could be discerned. The mucous membrane of the anus was as before described. The treatment at first consisted of topical applications—oxide of zinc, logwood, calomel ointment, &c. But seeing that the continued action of the bowels maintained the irritation, I directed attention to the means of arresting it. I adopted the plan of emptying the bowel by an enema early in the morning, and then introducing a sedative suppository, in the meantime using local remedies, and keeping the patient free from all exciting influences. These measures, followed by a tonic line of treatment, cold shower baths, and plently of exercise resulted satisfactorily.

In the second instance the association of the diarrhœa with the local state was still more manifest. Mrs. J., aged 38, had been many years before operated on for a very extensive fistula in ano; in consequence of its almost complete division, a considerable loss of power in the sphincter had resulted. On examination in her case, the muscle presented very little resistance to the introduction of the finger, and could but feebly grasp it when introduced. This produced a difficulty in retention, which increased her discomfort. A small pedunculated polypoid growth was seen immediately above the anal opening. This was removed by ligature: a well-marked fissure in addition to the general excoriation of the surface was present; this was incised, and soon healed. A similar plan was then adopted as in the former case, with the addition of blistering the sacrum and the administration of large doses of the brom. potass., which certainly was of benefit. Unfortunately for herself, this lady, expressing herself in the enjoyment of great and unaccustomed comfort, went last summer to Scarborough. While there a sad calamity, consisting of the drowning of two near relatives by the influx of the tide on the semi-circular coast between Filey and Scarborough, befel her. The consequent anxiety and grief produced an instant relapse of the old condition, and I regret to say that since her return to Dublin she has not benefited from treatment as much as might be desired.

Clinical Records.

CASE OF SEVERE ORCHITIS FOLLOWING PARACENTESIS.

By C. P. Coombs, M.D. Lond.

The subject of treating orchitis by puncture of the testicle is now before the profession; the possible results of a slight wound of the organ, as occurring in a recent case, are therefore now given.

A. B., aged 58, labourer, has generally been healthy, but suffered about three years ago from a bad carbuncle on one knee. He applied to me on October 7th, 1875, on account of a boil on the lower part of the right inguinal region in such a situation that the paid of his truss rubbed it. The sore was not much inflamed, but caused him discomfort. As the same side of the scrotum was very largely distended with serum, I told him it ought to be tapped when the sore had healed. Accordingly, on the 21st he came for the operation to be done. The right inguinal canal was very large, and the hernia came down directly the truss was moved away; I told the patient to keep the bowel up with his hand. The small exploring trocar was then passed into the sac of the tunica vaginalis, not so vertically as usual, for fear of wounding the sac of the hernia. Not much serum escaped, and the testicle certainly was large. The man complained of pain, but not much, and walked home (nearly two miles) directly after the operation. Next day he walked for many hours, being very wet part of the time.

On October 23rd, two days after the tapping, he sent for me, and I found his testicle was much swollen, and very painful. Opium was given internally (it was continued for some weeks), and hot fomentations applied to the part, but the testicle continued to swell, and the pain increased.

On the 30th a trocar was passed into the tunica vaginalis and some serum removed, with slight relief. At this period the patient had rigors, a brown tongue, small and rapid pulse, and some broncho-pneumonia. Tincture of bark with nitric acid was therefore given him.

On Nov. 2nd the testicle measured about six inches vertically, with a circumference of about twelve inches. A trocar passed into the body of the organ withdrew about three ounces of bloody pus, and slight reduction of tension was manifest. But this loss of size was soon made up, and another trocar incision was made to the depth of 1½ inch into the lowest point, where was a fluctuating point, but no matter issued.

This was on or about Nov. 8; and from this date the treatment consisted of linseed poultices to the swelling, while the internal use of cinchona, with a nourishing diet and porter, were continued.

A few days later the *skin* and cellular tissue of the lower part of the lower part of the scrotum were swollen, tender, and red, the skin of the upper part being tense and shining, but with no disposition to a point; no discharge had occurred from the trocar wound.

On the 25th Nov. a large escape of matter took place from the back and lower part of the scrotum, near the middle line, and the testicle began to diminish in size. The pus was apparently escaping from the gland into the cellular tissue, and thence through the skin. By means of carefully adjusted pads, bagging was prevented.

When seen for the last time, on Dec. 11th, the convalescent testicle was only about three times the size of the other, and the scrotum looked healthy, the wound having healed.

Remarks.—The case passed out of my hands in the middle of November; but at the patient's request I saw him occasionally with his new attendant, and from that time my notes of the case are only fragmentary. As the testicle was large, the quantity of fluid small, and the trocar directed backwards, it is fair to conclude that the testicle was wounded in tapping, but probably the injury was a mere scratch. The sore on the scrotum points to an unhealthy state of the system; the testicle itself cannot have been in a perfectly normal condition. Anyhow, some or all of these factors sufficed to bring the man into a most critical state. Of course it is possible that the testicle was in a state of subacute orchitis, and that the exposure to wet and extra exertion of the day after the tapping stirred up the more urgent inflammation. At the time of greatest swelling I was much tempted to make a free incision into the organ, but there was some uncertainty as to the position of the hernia, and whether the testicle was not the subject of some morbid process other than simple suppuration.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

The fifth meeting of the Society was held on Friday, February 4th, 1876, Mr. E. Hamilton President of the College of Surgeons, in the chair.

EXTENSIVE DISEASE OF THE BONES OF THE FOOT.

Mr. W. J. Wheeler exhibited the foot of a child 7 years of age, who was admitted under his care, to the City of Dublin Hospital on the 16th November last year. The history of the case was briefly as follows:—On the 5th November, 11 days before admission, she strained her foot or hurt it in some way, so that on the day of the 6th, when asked, she was only able to place the heel and the ball of the great toe alternately on the ground. On admission, the foot was merely swollen and somewhat clubbed in appearance. There was a ganglion in the extensor longus pollicis tendon, which disappeared under treatment. On the 4th December an abscess pointed to the direction of the base of the second metatarsal bone, which he opened, and on passing a probe down he came on diseased bone. The incision partially closed, a small opening only remaining. At a little distance from this there came a second opening, and the foot presented the appearance which it now did with the two papillæ which the Society now saw. Having made an incision and on examining the diseased structures they found an erosion on the base of the second metatarsal bone, and the three cuneiform bones were carious on their anterior, posterior, and lateral surfaces. The cuboid bone was also diseased on its internal surface, the scaphoid bone on its anterior surface, and there was likewise disease in the astragalo-scaphoid articulation. On the articular surface of the bones there were pits or depressions with well-defined edges. That had been stated to be diagnostic of scrofulous disease, but it was doubtful with what truth. There were also present annular ulcers, as described by Paget, or spots of ulceration with circular trenches round a worm-eaten surface. He thought the specimen possessed some points of interest, verifying Mr. Syme's observation, that disease of the ankle-joint (commonly so-called) was more frequently between the astragalus and the os calcis, and not between the tibia and the astragalus; and further corroborating the experience of writers on conservative surgery, and diseases of the foot, that when the disease commenced in the situation which it did in the case now before the Society, it was almost useles to attempt to remove any portion of the bone, the disease being so extensive; there being one synovial membrane common to the three cuneiforms—the scaphoid, the cuboid, the three cuneiform bones themselves, and between the two outer cuneiforms and the bases of the second and third metatarsal bones, and also between the external cuneiform and the cuboid. He operated on the child on Tuesday morning last, according to Mr. Syme's method, having first applied Esmarch's bandage, and the case had since been progressing most satisfactorily.

EXCISION OF THE BONE OF THE FOOT.

Mr. Croly exhibited a foot which he had removed on Tuesday morning last from a young man in the City of Dublin Hospital by Mr. Syme's method at the ankle-joint. The history of the case was briefly this:—About 8 months ago the wheel of a cart went over this young man's foot, and he was

placed under the care of his (Mr. Croly's) brother, Dr. Albert Croly, at Stillorgan, and he tried all the usual remedies to reduce the inflammation; but the boy being of a strumous habit, the inflammation resulted in the formation of a large abscess on the dorsum of the foot. He became a patient of the City of Dublin Hospital, and on a probe being passed down, it went into the sac of a large abscess corresponding with the cuboid and the three cuneiform bones. After consultation with his colleagues, Mr. Croly decided on trying the preservative operation, and he removed the cuboid and the three cuneiform bones, Esmarch's bandage having previously been applied, and seeing the cartilage sound on the rest of the bones, he determined to try and save the patient's foot. It was really very interesting to watch the case afterwards, because the granulations formed, and having removed these three bones, the foot seemed to be getting well. He was very glad to see such an improvement in the foot, and he thought the case likely to end well without any further operation. However, fresh abscesses formed, not only at the site where the bones were removed, but also over the scaphoid bone, and then the boy got symptoms of hectic fever, and was running down with it when he (Mr. Croly) removed the foot by Syme's method. He thought the interesting point in the case was the disease coming on, not from any constitutional cause, but from direct injury; then, the three cuneiform bones and the cuboid having been removed, the disease set up so actively afterwards as to necessitate the removal of the entire foot.

Dr. ROBERT M'DONNELL then made a communication on

TORSION OF ARTERIES,

which will be found on page 153. In the discussion which followed,

The PRESIDENT said the communication made by Dr. M'Donnell was one of great importance to the Irish School of Surgery, and, he thought, one they ought not to pass over without discussion. He might mention that very lately they had experience of the benefit of this mode of dealing with arteries in a case of amputation of the arm in a machinery accident. It might occur to some persons that torsion would not possibly stand the force of the circulation; but in the case he had referred to it was satisfactorily illustrated, inasmuch as after torsion the brachial artery used to protrude from the surface of the wound with immense force, and retract like the movements of the piston of a steam-engine, and there was not the least discharge of blood from it. In that case the wound was contused a good deal, but still, by the use of torsion and antiseptic surgery, the wound united without the formation of a single drop of matter. In that case he was at one time himself inclined to adopt the plan of the antiseptic ligature of catgut, but he had lost all faith in that treatment after a case of secondary hæmorrhage from a catgut ligature. He was therefore in favour of torsion as contrasted with catgut ligature.

Dr. BARTON said that for some years in the Adelaide Hospital he and Mr. Richardson had adopted torsion, and had every reason to be very well satisfied with the results. There were one or two points, however, that from time to time engaged their attention that he might refer to. In some of the very small vessels close to the periosteum, to which he (Dr. M'Donnell) had alluded, he found it impossible to secure them very satisfactorily by torsion. It might have occurred from their not being provided with forceps with a sufficiently narrow beak, and at the same time provided with teeth, but it certainly did occur with ordinary forceps that in those small vessels bound down by the periosteum, or by firm fascia, the operation was not so readily accomplished as to induce the surgeon to waste time over them. They had, however, invariably found in large wounds that the larger arteries did remarkably well. They had frequently held the femoral artery with the catgut ligature. Mr. Richardson's *presse artère* answered the purpose very well, and was allowed to remain on an artery the size of the femoral for about four days, and it did not interfere with the healing of the wound. But for years Mr. Richardson and himself (Dr. Barton) had adopted torsion, and had found it answer in every way, and he believed it had materially aided in the successful treatment of wounds, inasmuch as it avoided the presence of any foreign substance in the wound. He would like Dr. M'Donnell in his reply to state specially how he used the ligature so as always to break it off in the proper spot, for that did not turn out very successful in his hands, and he gave it up for the torsion forceps.

Mr. CROLY said he might mention that when torsion was re-introduced by Professor Syme he got a pair of his torsion forceps, but having found them not so satisfactory in practice as he desired, he gave them up. He confessed that he did not probably take time enough with those forceps, and occasionally he found the teeth of the forceps entangled. He would then throw the forceps aside and ask for the ligature, especially as at that time Professor Hargrave was in the habit of saying "Throw aside your torsion and put a good ligature on." Sometimes he (Mr. Croly) twisted arteries, and sometimes he tied them. Lately he happened to pay a visit to London—the week after Christmas—and he was certainly greatly struck with the way in which torsion was performed in the London hospitals. Amongst these institutions he went to Guy's, where he saw Mr. Bryant use a torsion forceps which he (Mr. Croly) now had the pleasure of exhibiting to the Society. (*Forceps exhibited.*) He (Mr. Croly) was greatly struck with the facility with which Mr. Bryant and others twisted all the arteries. Mr. Bryant mentioned one case to him which he (Mr. Bryant) considered to be a very instructive one. A lady had an aneurism of the facial artery: he cut down over the facial artery to divide the artery across with a scalpel, twisted both the ends, closed the wound by the antiseptic method of carbolised gut, and it united by the first intention, and the aneurism was there and then cured. He saw Mr. Durham and Mr. Bryant operating, and he saw them slipping the little forceps (just now exhibited) on the arteries and twisting them with considerable facility. He (Mr. Croly) went at once to Mr. Millikin's and obtained a pair of those forceps. Mr. Bryant told him that this artery forceps was the one in which they had the greatest confidence in in Guy's Hospital. The other morning he (Mr. Croly) had a Syme's operation in which he twisted the anterior tibial and plantars, and the forceps answered admirably. He closed the wound by Lister's method, and twisted the arteries, and he had no trouble with them. As far as he was concerned, he was strongly in favour of torsion. At one time he was in favour of acupressure, but he thought that practice had been almost entirely given up. He thought they should all give torsion a good trial, and especially now that they were so much in favour of the antiseptic treatment of wounds. He was determined to give torsion a full trial.

Dr. SWAN remarked that while at Steevens' Hospital, when the ligature was used, he had seen a good many stumps opened for the purpose of arresting secondary hæmorrhage. Such a practice was now, however, unknown. The first habit of the surgeon used to be to multiply the number of ligatures, and some tried created irritation. More time was now taken in securing vesssels by torsion, and small vessels that would otherwise escape the application of the ligature were now secured.

Mr. B. WILLS RICHARDSON inquired what were the largest arteries that Dr. M'Donnell had twisted?

Mr. W. J. WHEELER said he had an opportunity of trying the plan that Dr. M'Donnell recommended with smaller arteries, and adopted the means described in his pamphlet, that of the silk ligature attached to two pieces of wood, and on the three occasions that he (Mr. Wheeler) used it he never found any difficulty. They all broke at the knot, as Dr. M'Donnell had described. On the other two occasions on which he (Mr. Wheeler) twisted arteries—one was the radial artery, and the other a small artery situated in the neck, and opened as the result of a wound—on both those occasions hæmorrhage followed. That might have been from the torsion not being sufficient. In the case in which he cut through the internal and middle coats of the artery with the silk attached to the wood, as suggested by Dr. M'Donnell—that case was perfectly successful, and no hæmorrhage followed.

Dr. M'DONNELL, in the course of his reply, said that, with regard to Dr. Barton's inquiry, he had merely stated that which was a matter of fact. The best way he could show that was by performing that part of the operation. There was no fear but that the silk broke at the knot. (Dr. M'Donnell then demonstrated this fact successfully by fastening a silk ligature around a portion of an artery, the silk breaking at the knot, and the artery being firmly caught.) The vessel was now perfectly secured by twisting it. Large vessels were the ones on which it was most convenient to use the ligatures. Mr. Richardson had asked what sized vessels he (Dr. M'Donnell) had twisted. He had twisted the radial, the brachial, the popliteal, and the femoral; the femoral was the largest. He would not, however, have the slightest hesitation, if it were needful to do so, to twist the external iliac and

nothing could possibly be more complete than the occlusion which such a vessel would give. It had been proposed by Mr. Colles that this mode of occluding vessels might be used in continuity. He (Dr. M'Donnell) knew that in torsion there was nothing new, nor did he claim anything new for it; he merely urged upon the members of the Society what he believed to be an admirable practice, and one which was of far greater moment now than formerly. Their object now was to have their convalescence as rapid as it could be, and it was in that view that he thought torsion had now a value far beyond what it had in former times. In torsion they had very much the choice between the catgut ligature and twisting, and of those two he could not help thinking that, from consideration and what they had seen, torsion was the best and most secure, because it gave complete and intact the vessel within itself, and they could hardly fancy that a vessel in such a position could ever burst or begin to bleed again; at all events, they knew that if the catgut ligature was used there was nothing to prevent the vessel being trumpet-mouthed and open; even in John Hunter's own case the vessels gave way, and were trumpet-mouthed, and the process had not gone on. He (Dr. M'Donnell) supposed they never would get a means absolutely certain, but as far as their knowledge went the method he had been describing made the occlusion of the vessels as complete as human skill could make it.

Mr. SWAN then read his paper on

NERVOUS DIARRHŒA IN FEMALES,

which will be found on page 155.

Mr. F. T. PORTER asked Mr. Swan whether he considered the affection peculiar to females. During the past month he had had two very troublesome cases in gentlemen—in both caused by anxiety of mind.

Mr. SWAN said he had never met the disease in men. No doubt the circumstances that Dr. Porter had alluded to were the fact, but he (Mr. Swan) had no knowledge of them, and therefore he could not furnish an answer to the question put.

The Society then adjourned.

PATHOLOGICAL SOCIETY OF DUBLIN.

AT the meeting held on Saturday, Dec. 11, 1875, Dr. HENRY KENNEDY, President, in the chair,

Dr. THOMSON said the specimens he exhibited were removed from the body of a man, aged 74, who died in the Richmond Hospital in the early part of last summer. He presented himself at the dispensary and complained of urgent urinary symptoms, and at the time presented many of the prominent points which led to the belief that he was suffering from urinary fever. He was at once admitted to hospital and placed under treatment. On examining the rectum, being guided to that by the symptoms which the patient had described, a very large tumour was found, caused by the enlarged prostate. He was suffering very great irritability of the bladder, and was unable thoroughly to empty it. He (Dr. Thomson) at that time thought he had simply to deal with a case of enlarged prostate, having regard to the fact of the man's age and the history of the case. He said he had never had any trouble with the urinary organs until three months previous to his admission to hospital; from that time up to about a week before admission he had simply suffered from occasional irritability of the bladder, and the need to pass water frequently during the night. The symptoms presented rather led to the belief that he was suffering from retention, caused by the enlarged prostate, and he was accordingly treated for that. He (Dr. Thomson) thought, however, that in addition to the large prostate it was quite possible that the patient might have a calculus, but in the condition in which he then was—a high state of fever—the cystitis that he was then suffering from he (Dr. Thomson) did not deem too excessive to do more than pass an ordinary elastic catheter and relieve the bladder of the urine. The symptoms got worse, and the patient died a fortnight after admission. At the post-mortem examination the bladder presented all the ordinary appearances which were found in cases of chronic cystitis. At the anterior portion of the bladder was found a small pouch, into which probably a mass about the size of a playing marble would fit, and the tissue was extremely thin. Upon further examination it was found that a quantity of pus had passed through a small frayed opening in the bottom of this pouch into the pelvic cavity. On examining the kidneys it was found that they were both the seat of very extensive disease. In the left kidney it was perceived—firstly, that the whole surface of it was thickly studded with a number of small abscesses, which looked at the time very like a number of pustules; they varied in size from a grain of wheat up to a fourpenny-piece; they were scattered closely all over the surface of the kidney. On the left side the covering of the kidney had been separated and formed into a large cavity which was filled with pus. The whole surface of the other kidney was covered with small pustules or abscesses, and in both cases the substance of the kidney was greatly disorganised. They found in addition to this that the suggestion which he (Dr. Thomson) made at the time the man was under treatment, as to the possibility of a calculus being in his bladder, was correct. Dr. Thomson then exhibited a beautiful specimen of oxalate of lime calculus, one which was sufficiently common, generally speaking, but in this country it was not so very often seen. It was otherwise known from its general character as the mulberry calculus. The points of interest in connection with the case were the fact of the calculus being found in the bladder, in which the symptoms certainly had not existed for many months, and the possibility of that might be accounted for by the presence of the pouch, of which there could be no doubt, and that possibly the calculus was for a certain time encysted in it, and finally made its way into the general cavity of the bladder and set up irritation. There was no peritonitis.

Dr. JAMES LITTLE said the specimen he wished to bring under the notice of the Society exhibited in a tolerably typical manner the usual characteristics of malignant disease of the liver—what was called Farr's tubercle of the liver; that was that they found on the surface of the liver in that position usually occupied by malignant disease a number of tubercles which stood out and were sharply defined from the surrounding liver structure. They varied in size from the circumference of a threepenny piece to one at least of that of half-a-crown, and they all presented very distinctly the depression in the centre. They were all in that condition which appeared to arise from destructive atrophic changes taking place in the centre of the malignant mass, while it was spreading in its circumference. The specimen also presented the usual features of malignant disease of the liver in the fact that it was secondary to malignant disease of the stomach. On laying open the stomach they perceived a mass which was much more fungoid when the specimen was fresh than now, and which the history of the case justified then in believing was the original disease. There were two features, however, in the case which were somewhat uncommon. One was that a large portion of the left lobe of the liver had undergone destruction. There was what might be called in a vague way an abscess formed in the left lobe of the liver. It was not a truly inflammatory abscess, such as was accompanied by the formation of matter—it was rather gangrenous, and he believed it was caused by malignant disease which destroyed the nutrition of the vessels that kept up the integrity of that portion of the liver. There was also matter formed between the upper surface of the liver and the diaphragm, and pleurisy existed at the lower part of the right lung. The clinical history was mainly interesting from the fact that, although for a short time before death it was tolerably apparent the nature of the disease from which the man was suffering, during the greater part of his residence in hospital the symptoms were not sufficiently distinct to lead to a direct diagnosis. The man was ill from January; the symptoms had been comparatively vague—loss of appetite, gradual loss of flesh and strength, some uneasiness in the epigastrium and right enchondroma. He complained of pain, and latterly of continuous pain, but it was of that dull, comparatively undistressing character, which they would hardly believe would indicate such a large amount of disease. However, one thing which he thought would often justify a belief in the existence of malignant disease was present in this case, and that was that the mental condition of the patient was one of peculiar apathy. The diagnosis he (Dr. Little) made in the early period of the case was that it was an example of abscess of the liver, due to residence in the tropics, and he believed the patient had simple disease of the liver. His symptoms pointed to hepatic disease, and while in hospital on three occasions he had three well-marked rigors. The interesting points in the case were—first

that it presented the typical appearances of Farr's tubercle of the liver; that it was secondary to malignant disease of the stomach, as was usually the case; thirdly, that a large portion of the left lobe of the liver had become destroyed, and was converted into a gangrenous mass; and lastly, the formation of pleurisy and the formation of purulent matter between the upper surface of the liver and the diaphragm. The clinical history of the case was marked by the comparative slightness and indistinctness of the symptoms. The loss of appetite was worth noticing. In the beginning of malignant disease of the stomach, he thought the first symptom was the persistent loss of appetite. The usual complaint of the patient had been that he felt as if he had always eaten something that was too rich for his stomach, and that he did not care for anything else.

Literature.

THE DISEASES OF THE HEART AND OF THE AORTA. (a)

[CONCLUDING NOTICE.]

THE seventh chapter is on "Disease of the Lining Membrane of the Heart," and is divided into endocarditis and structural disease of the valves. The author alludes to the great rarity with which endocarditis exhibits itself, except in union with the rheumatic diathesis. We agree with him in this. At the same time both endo- and pericarditis we know do occur *per se;* that is, not being attended with the special diathesis, nor any form of rheumatism being present. There is one form of pericarditis too which we rather think has not been as clearly recognised as it deserves to be. It might be called the strumous form. It is a disease *per se*, exhibits itself very usually in patients of both sexes from twelve to fifteen years of age, and is in every respect analogous to the disease which so frequently attacks the pleura. In these cases the contents of the pericardium when examined after death are those which would be called strumous, and tubercles frequently exist. We repeat, it seems to us important to recognise this form of disease. Amongst the causes of pericarditis the author speaks of cold, and quotes a case given by Stokes, in which this seemed to be the immediate cause. We have seen a similar case ourselves. An elderly female, who never had rheumatism, had occasion to get up during a cold night. She was seized with rigor while still up, and severe pain over the heart. All the symptoms of pericarditis developed themselves with extreme rapidity and violence, and she died on the third day. On examination the pericardium contained a quantity of a very dry lymph, presenting itself in masses as large as a walnut. On the question of the relative frequency of endo- and pericarditis we would agree with those who look upon the former as by much the most frequent affection, and of course attacking the left side of the heart. On this point our author holds that acute pericarditis is more common than acute affection of the valves. We are at a loss to explain this opinion. For all our experience goes the opposite way; and on the very next page (797) we read: "Hence it may be assumed that the mitral valve is, *par excellence*, the seat of acute endocardial inflammation." The author notices the interesting fact that before birth the right side of the heart is the part which commonly exhibits disease. We must say this is new to us, and is certainly of importance. He attributes it to the oxidised blood from the placenta going directly to the right cavities of the heart: and this would seem to be a rational explanation of the fact Into the causes of the valves being attacked we need not enter, further than to say that the opinion which makes lactic acid a cause of acute rheumatism, as shown by Foster, seems to us absolutely proved. This was first shown by Richardson in animals, and then confirmed in the human subject by Foster. The question may, we think, be asked here, Is lactic acid the only cause? May not other agents effect the same end?

After a very full account of acute endocarditis the author enters into the question of the treatment of such cases; and we are very glad to observe that he advises the adoption of a cautious antiphlogistic plan. With the writer, we entirely ignore the scepticism which is so widely diffused at present, and which it appears has been advocated by Niemeyer, who was quite sceptical of all modes of treatment. We would even go further than our author, for he seems to think that a complete cure is not to be expected. We believe it may; and can see no reason why what we see occurring in the eye may not also occur in the heart. There is one point on which our author dwells which does not exactly square with what we have seen; we mean the frequency with which the walls of the ventricle are affected at the same time with the valves. The writer speaks of it as being common at first. With ourselves this has not been so; we mean in first or second attacks. Subsequently it is to be observed, and then has a most important bearing on the future of the case. Some of the returns given by the author as to the frequency of special valve disease are worthy of notice here. He takes them from post-mortem examinations made by himself in 44 cases. Thus, he states aortic valve disease is essentially a disease of advanced life, and of the male sex; whilst its cause, amongst the working classes, is the abuse of strong drink, and amongst the wealthier classes is gout, or the lithic acid diathesis. And again, out of 26 cases of disease of the aortic valves only 2 were associated with rheumatism. The author thinks that sudden death in aortic valve is very exceptional, and in this we agree with him; and further, that when it does occur degeneration of the heart's structure exists. In the treatment of the affection the author alludes to the importance of the views put forward so far back as 1832 by Sir D. Corrigan, who, at that period, not only deprecated the use of digitalis, but recommended a tonic line of treatment, in which he has been fully borne out by all subsequent writers. It is right to observe, however, that our author states this drug may be given provided its depressing effects are guarded against by combining it with such a tonic as iron or ether. Several cases, some illustrated by tracings of the pulse in this peculiar form of valve disease, are very fully given by the author. (a)

A large part of this same chapter is devoted to the consideration of disease of the left auriculo-ventricular opening. On this subject a considerable difference of opinion exists as to whether narrowing of the opening, stenosis as it is now called, can be diagnosed. Our author states that it can, and he founds his opinion mainly on the presence of two symptoms, which are, first, a presystolic murmur, and secondly, fremitus. We do not profess to give an opinion on the exact time the murmur is heard in these cases, and it is on this, the author states, the exact diagnosis depends. For ourselves, the place where the murmur is heard loudest and the circumscribed area it occupies have been the grounds for making our diagnosis; and we believe this means will very seldom deceive us. Still we admit we have been mistaken, and have looked for disease of the opening where examination after death proved none existed—either stenosis or dilatation. What did exist was fatty degeneration of the wall of the ventricle, especially close to the opening, and slight dilatation of the ventricular cavity. The mitral valves were healthy, and there had been no fremitus.

(a) "The Diseases of the Heart and of the Aorta." By Thomas Hayden, Fellow of the King and Queen's College of Physicians; Physician to the Mater Misericordiæ Hospital; Professor of Anatomy and Physiology in the Catholic University of Ireland; Member of the Royal Irish Academy; Corresponding Member of the Accademia Fisio-Medico Statistica of Milan, &c., &c. Illustrated. Dublin: Fannin and Co., 41 Grafton Street. London: J. and A. Churchill. 1875. Pp. 1232.

(a) The author expresses his thanks to Drs. Nixon and Grimshaw for these tracings.

The murmur which occupied the first sound was not constant, and was distinctly louder on some days than others. Whether our author would have made a correct diagnosis of such a case we will not take on us to say. Speaking of fremitus in these cases, we must observe that it is in our experience rare, much more so than it was with our author. Whenever or wherever it exists, however, we have ever considered it a strong proof of the existence of organic disease. Besides the subjects we have noticed, the author has also treated in this chapter of disease of the pulmonary artery, narrowing of both auriculo-ventricular openings, and disease of the coronary arteries. Though much interest attaches to these affections, we do not feel it necessary to allude to them further here.

Chapter VIII. is on "Formation and Migration of Blood Clots." This, though a short, is a very interesting chapter, and includes the subject of embolism and phlebitis. According to our author, the right side of the heart is by many degrees more frequently the seat of thrombosis than the left, and this he attributes to the greater weakness of the right cavities, which is, of course, greater when disease, such as dilatation, exists. For ourselves, we are under the impression that these affections—embolism, thrombosis, &c.—are more common of late years than formerly; and if asked for an explanation of this, we would set it down to the tendency of the present day to feed, or, we should rather say, overfeed patients. The orders now so constantly given to keep up the strength are overdone, and, we believe, often lead to mischief, especially the affections treated of by our author in this chapter. But the point is too important and extensive to enter into further here. The author speaks of capillary embolism in the extreme vessels, and of the effects which result when the brain is the organ attacked. We do not, however, notice here any allusion to the opinion advanced recently by "A London Physician"—we forget his name—to the effect that chorea was caused by this state of the vessels in certain parts of the brain. To us this appears a very doubtful point, and is hardly to be reconciled with the fact that in the great majority of instances sleep puts an end to the choreic movements. The subject, however, seems worthy of further consideration.

Chapter IX. is on "The Neuroses of the Heart." This includes such affections as hysterical, dyspeptic, and gouty palpitation, and the same arising from anæmia, cardiac asthma, angina pectoris, and exophthalmic goître. The reader will find some interesting cases detailed of palpitation resulting from the over-use of tea, and this, though not a fatal disease, is one often of much consequence to recognise, and far more frequent than is usually thought. The account of angina pectoris is very concise and good. The author considers it essentially a neurosis, and we believe he is right. The several causes, however, which have been considered capable of inducing the affection are all given. Some of these, as our readers know, are organic, such as disease of the coronary arteries and fatty degeneration of the heart itself; and there can be little doubt that, when present, they give a strong tendency to the development of the symptoms known as angina pectoris. But it must not be overlooked that the two organic diseases named often exist, and yet no angina declares itself; and, again, angina may declare itself where there is no real disease. We believe spasm plays an important part in causing this grave affection.

The concluding part of this chapter is taken up with the remarkable disease known as exophthalmic goître. The account of the disease is very full, and the details of the examination after death of some cases are also given. Fatal cases of this disease are so rare that these details are the more valuable; but as our space is rapidly lessening we cannot enter further into this interesting subject here.

The tenth and concluding chapter is on "Diseases of the Aorta." This, of course, includes aneurism of both the thoracic and abdominal aorta. Need we add what an endless variety of forms and phases this disease exhibits? Every half-inch of the vessel, from its origin to its division into the iliacs, has its own story to tell; hence it scarcely comes within the reach of probability that any one writer can advance all that is known on the subject. Yet our author has managed to bring into this chapter a great mass of interesting and practical matter—more, indeed, than exists anywhere else on this disease. It was right, too, that, in a medical aspect, aneurism should have been treated in a masterly way, for Irish surgeons—and foremost amongst them the late Dr. Billingham—have brought the treatmsnt of external aneurism to a great state of perfection, and gained the most important step since the days of John Hunter; and now, again, the Irish School, in the person of Mr. Tufnell, have gained a most important step in the treatment of internal aneurisms, and proved, as it appears to us, that this terrible disease can be deprived, in part at least, of its terrors. How far the plan may become general and applicable to the majority of cases remains yet to be proved; but that it can effect a cure in some instances seems certain. For the details, however, of the plan, we must refer our readers to the work before us; and, indeed, we find we must now bring to an end our notice of this work. In doing so we would venture to suggest to the author the prudence of dividing his next edition into two volumes. The cases, too, we think, might be printed in smaller type, if, indeed, he would consider it advisable to give them all again in detail. The divisions, too, of the chapters, and the several forms of the diseases of the heart, might, we think, be more distinctly divided than they are; it is quite true there is a very elaborate index, but readers like to see these matters in the table of contents, and so we suggest them to be placed there. With these few suggestions we take our leave of this work, and in doing so feel that our notice of it has been meagre in the extreme. It has not reached even to a sketch, but is a mere etching, for in truth the work is a great one, and, considered as the result of the labours of one man, a vast undertaking. In the preface the author returns his thanks specially to Drs. Duffy and Nixon for their valuable help, but, great as it was, it must have constituted a very small portion of the labour spent on the work. That it will be the standard volume on diseases of the heart, and for a long period to come, we cannot doubt. The research displayed in it is of the most extended kind, and the anatomy and physiology of the organ most elaborate, and up to the very latest knowledge of the day. The engravings, too, and tracings are very well executed. But above all, the personal experience of the author seems to have been very extensive, and has thrown over the entire work a practical aspect which must commend it to the approval of the profession at large. For ourselves, we cannot speak too favourably of it.

THE YEAR-BOOK OF PHARMACY. (a)

THE Year-book of Pharmacy for 1875 recently published contrasts favourably with any of its predecessors. There can hardly be a question as to the value of these periodical retrospects of science; were it only as a means of facilitating reference, they must prove an incalculable benefit to those for whom they are compiled.

It is of the utmost consequence that the editing of such publications should be undertaken in a spirit of rigid impartiality, and in such a spirit we are satisfied Mr. Siebold has approached his task. Great care seems to have been expended in the selection of papers, and we are especially pleased to see that foreign pharmaceutical literature has not been slighted.

The plan of the book is similar to that hitherto adopted. It opens with an admirably written introduction, from the pen of the editor, in which he summarizes the chief papers of interest which are given in the body of the volume. The first 400 pages constitute the "Year-book" proper; the following 250 pages being devoted to the

(a) "The Year-book of Pharmacy for 1875." London: J. and A. Churchill. 1875.

Transactions of the British Pharmaceutical Conference. When we mention that under the headings "Pharmaceutical Chemistry," "Materia Medica," and "Pharmacy," abstracts are given of no less than 270 papers, and that these are followed by copious "Notes and Formulæ," we shall have given some idea as to the extent of ground gone over. Some extremely valuable papers are given in full as having been read at the British Pharmaceutical Conference. We regard the work as being a careful as well as a copious record of the progress of pharmacy at home and abroad, and as being highly creditable to all concerned in its publication.

ZOOLOGY IN IRELAND.

ALTHOUGH it is not strictly our function to review the management of scientific societies, one cannot allow the annual report of the Irish Zoological Society to pass *sub silentio*, inasmuch as it seems to us to embody one of the most flagrant manifestations of incompetency of administration and misuse of public money which a public society has ever been guilty of. The Royal Zoological Society of Ireland does not conduct its operations under any difficulty except that of its own creation. It possesses the only zoological collection in Ireland—is one of the very few places of amusement which strangers can visit in the daytime—is seated rent-free in a beautiful part of the Phœnix Park—is subsidised by Government with a yearly grant of £500—and has received large additional sums for purposes of improvement. Despite these advantages, of which a private speculator would have made a fortune, the society has dragged out its scientific existence for years under the pressure of unremitting impecuniosity, and has lived rather by begging for subscriptions and mulcting the working classes than by offering an attraction to visitors. Every effort to stimulate the society into efficiency has been futile, and even three yearly grants of £2,000, made to it some few years ago, proved inefficacious to excite any interest in the Gardens, having been mostly spent on comforts and decorations for which the public or the animals cared nothing.

Three years ago the usual state of semi-bankruptcy of the society having become unusually inconvenient, and the subscribing public of Dublin having been thoroughly begged out, the managing Council fixed upon the ruinous idea of increasing the income, not by improving the attractions of the Garden or reducing the expenditure, but by doubling the price of admission and keeping the stock of animals at a minimum, of which more. The present annual report gives the natural result. In the year 1873 the cost of admission on week-days was sixpence, and for the working classes on Sundays one penny. In that year nearly 148,000 persons visited the Gardens, and the gate income was £1,450. The next year, 1874, when the Council had raised the admission fees to one shilling for week-days and twopence for Sundays, the attendance fell to 109,000, and the income was less than before by a few pounds; and in the year 1875 the attendance has again gone down to 104,000, and the income stands about the same. It thus appears the society has sacrificed 42,000 visitors, has shut out nearly one-third of its patrons for a nominal money gain, or no gain at all, and the working and middle classes have been excluded in great numbers from the Gardens in a useless and prejudicial attempt to make good by a forced income the long-continued shortcomings of administration.

But a further perusal of the report illustrates still more forcibly the miserable condition into which the present practically self-elective Council has brought the Royal Zoological Society. As a scientific body, it is and has always been a nonentity; as a place of popular amusement, the attractions of its gardens have dwindled to the most contemptible meanness. Its subscription income of 1875 is barely more than two-thirds of the amount at which it stood in 1874, and is (with one exception) less than it has been for any year since 1870. Its stock of animals is less in number than it has been for seven years, and the void created by the death of handsome and interesting carnivora and reptiles has been filled up by the addition of dickey-birds to the collection, every one of which is taken credit for as an "animal" in the report. This dearth of zoological attractions is accounted for on an examination of the sums spent in purchase for the last ten years, which shows that the Council could in the past year afford to spend only £107 in keeping up their collection, the most pitiful outlay of the last nine years. Lastly, the report records the death of the old lioness, the principal attraction of the Gardens, and the mother of successive broods of young lions, the sale of which brought no less a sum than £1,400 to the income of the society.

In view of all these facts, and of the further circumstance that the society's over-draft at their bankers has nearly trebled since last year, we are astonished to observe that the Council consider the state of the Society as "satisfactory." So far from concurring in this view, we regard the Society as bankrupt alike in purse and public interest. It has within the year lost one-third of its subscribers and nearly one-third of its visitors, its stock-in-trade has run down to the lowest ebb, and it has no money to buy more. The most interesting and most money-making animal in its collection has died, and its coffers are tenantless, and all this is what the Council

calls "satisfactory." If the Gardens were a private speculation we might be content to take no notice of these facts, but as the society claims to be regarded as a scientific and educational institution, and receives a considerable sum from the public funds each year on the faith of this character, we hold ourselves entitled to protest against the system of management which has brought a prosperous and useful society to such a melancholy decadence.

THE MEDICAL INSPECTORSHIP OF THE IRISH LOCAL GOVERNMENT BOARD.

THE appointment of Dr. Croker King to the office of Medical Commissioner of the Irish Local Government Board, in the room of Dr. John MacDonnell, being a settled affair, the profession in Ireland is concerned about the succession to his office of Medical Inspector. The selection of Dr. Croker King can give no occasion for cavil, for, though we do not regard his fitness for the post as equivalent to that of the other leading competitor, Dr. Rawdon Macnamara, nevertheless Dr. King has proved himself an excellent public officer and a man of intelligence and independence of mind, and his advancement would deserve approval on the principle of promotion within the service if he possessed no merits of his own. It has long been felt that the Medical Commissioner has not exercised his full influence in the deliberations of the Local Government Board, and that the acts and policy of the Board have thus been allowed to lapse into the hands of the Vice-President, who has shown himself before the Parliamentary Committees and on other public occasions by no means a partisan of the medical profession. Dr. Croker King's public career shows him to be a man who can form a strong judgment, and, if necessary, defend his opinion and maintain his authority, and, in this sense, he is distinctly the right man in the right place. The apprehension of an abolition job felt by the profession in the case of the Medical Commissionership is now shifted to the Inspectorship, and a strong fear exists lest an attempt may be made to get rid of another doctor and fill his place by some relative or friend of those in authority. A few years ago the number of medical inspectors was fixed by the Poor Relief Acts, and it would not then have been possible to occupy Dr. Croker King's place with any but a medical man; but since then, on the reorganisation of the Local Government Board, powers were taken to substitute lay inspectors. We have good warrant for the belief that there is at present no intention on the part of the Local Government Board to appoint any but a medical man, and that the reports as to the advancement of a lay *protégé* are without foundation. It by no means follows that the importunities of hungry candidates with parliamentary and personal influence to aid them may not induce the commissioners and higher authorities to waver in this resolve, and we therefore take leave to say, on behalf of the profession, that, so far as it has power to offer resistance to the substitution of a layman for the medical inspector, it will contest the point. Looking at the matter from its narrowest point of view, we observe that the medical inspectorship is a part of the already infinitesimal patronage which Irish medical men have a chance of enjoying, and a large class of useful public servants ought not wantonly to be deprived of one of the very few inducements to industry and activity which are within their reach. But to take a wider view, we would point out the indiscretion of taking the immense Poor-law medical organisation of Ireland altogether out of medical hands and entrusting it to lay inspectors, who *cannot* be capable of working it satisfactorily. Within the limits of the Poor-law Medical Service, or of those who have held office under that service, there is no lack of competent candidates, and we have already recorded the names of Dr. Whistler and Dr. Kerans as possessing claims to consideration. We hope that no inspector will be appointed, no matter what his other qualification may be, who has not followed the plough in the work of the Poor-law service. Of such men perfectly qualified for the position there is no lack, and it would be intolerable if their claims to promotion were ignored in favour of a *protégé*, however high his family qualifications may be.

"SOCIETY FOR THE ABOLITION OF VIVISECTION."

How much longer will humanitarian enthusiasts indulge their passionate indignation at the "horrors" of vivisection? How long will this "Society" mania of our times last? No sooner does any subject attract more than usual attention, or become the pet nurseling of some small and insignificant clique, than a society is at once started to ventilate its merits, to claim for it an importance to which it has no title, and by all kinds of exaggerated statements or misrepresentations to force public opinion to endorse views which, owing to their extravagant nature, are shared only by a few. That some of the societies are really useful institutions, have undoubtedly a *raison d'être*, and supply a public want, we will not hesitate to admit. But good, bad, or indifferent, there is no denying the fact of their rapid multiplication within the last few years, and of the frequency with which men on the slightest provocation rush together to form themselves into a "society." It would be tedious to name one half of these institutions, or to think of how many more are looming in the future. But the latest and most remarkable novelty of all is the "Society for the Abolition of Vivisection." We really wonder what next! Surely nothing less than a "Society for the Abolition of Fox-hunting, Coursing, &c.," a "Society for the Protection of Animal Life and Abolition of Animal Food," and other like institutions, whose object would not be much more questionable than that of the society on which we are now commenting.

It is not so much our intention to find fault with the object which the anti-vivisectionists have in view as the way they set to work in order to attain that object. Their case against the practices of certain scientific men may or may not be a good one, but, good or bad, we have a right to expect that it should be conducted in an impartial spirit, with a due regard to truth and justice, and with some degree of courtesy towards gentlemen whose profession has generally secured for them the good opinion and gratitude of the public. To write long letters or advertisements in the newspapers misrepresent-

ing the motives and the practices of a few medical or scientific men, and to charge them with being dead to the common feelings of humanity, is certainly not the way to obtain the sympathy and respect to which in some measure the promoters of the society in question may justly lay claim. And the steps which they have taken are the less defensible considering there is already an old and excellent society, which would have been perfectly competent to attain, as far as can be attained, the object which this new society has in view, and considering that a Government Commission has been thoroughly sifting the whole matter, pending whose report a respectful silence would have been more commendable.

The advent of this newly-fledged society has been announced by the insertion in the public newspapers of a long and inflammatory advertisement, in which, by means of a little sensational language, and copious extracts from a recent work on physiology, the anti-vivisectionists endeavour to arouse the indignation of the public at the fearful atrocities committed by such callous and hard-hearted individuals as Drs. Klein, Burdon Sanderson, and Brunton. The animus of this advertisement, which occupies nearly a column of the *Times*, is shown by the motto with which they have headed it—"O that mine adversary had written a book." A more appropriate motto could not have been chosen. It is so consonant with the party spirit by which the promoters of the movement have been influenced throughout, and with the unfounded aspersions that have been cast upon the motives, the objects, and the moral feelings of men of science. Equally significant with the above motto is the tail of this "Appeal to the Men and Women of England," in which we are informed that "the Society for the Abolition of Vivisection has no connection with any other society." We should think it had not. But the information was scarcely necessary, for we were not likely to suppose that any other society would be ambitious enough to claim any relationship with it. No, it stands alone—a striking manifestation of the humanitarian revivalism of the nineteenth century, and of the alacrity with which a few benevolent people, forgetful of the adage that "charity begins at home," rush from the pain and misery which afflict their own species in order to soothe the dying moments of guinea-pigs and rabbits.

But let us for a moment turn to the "abhorrent volume" which our censors hope "will ere long be committed to the flames." The number of extracts paraded in the advertisement is about fifteen, and as the object of this Society is to make the public believe that they are not overstating their case, and to lead the public to entertain the same false impressions of vivisection which they themselves entertain, we may presume that these extracts are the most "sensational" they could find. And what does their exposure amount to after all? Space will not allow us to go through them *seriatim*, but with one or two exceptions, which we will notice presently, there is not one of these extracts which shows that the mode of dying or the pain preceding death is one whit worse than the animal would have experienced when hunted in the field, killed by the sportsman, or allowed to die a natural death. In order to make vivisection appear particularly repulsive in the eyes of the public, the Society lays great stress upon this "abhorrent" volume being entirely for the use of students and an educational work. But this way of putting it is only calculated to grossly mislead the "men and women of England" who are asked to "force" themselves to read the extracts that have been chosen. We all know that the gentlemen who, from a love of scientific research, are induced to work in the physiological laboratory will form but a very small percentage of the whole number of hospital students. As it is it is difficult to get men to work in the dissecting-room as they ought to do; and the amount of time, labour, and perseverance required for experimental research, to say nothing of want of inclination, would always restrict the number of students in practical physiology.

In fact, the whole movement—the attempt to excite the indignation of the public by misrepresentations and sensational appeals, the impeachment of the humanity of a few gentlemen devoted to the advancement of science, and the establishment of a society for the express purpose of forcing the Legislature to pass a "law for the total suppression of vivisection under any scientific pretext whatever"—is, we do not hesitate to say, a mistake. We can no more make people humane by Act of Parliament than we can make them moral. If the few gentlemen who now and then perform vivisection were let alone, it is not at all probable they would abuse the liberty vouchsafed to them. Men who practise such a profession as that of the art of healing are the last men in the world to be dead to feelings of ordinary humanity. As every schoolboy has been taught—

> "Scilicet ingenuas didicisse fideliter artes,
> Emollit mores, nec sinit esse feros."

We will not deny that occasional instances might occur in which physiological investigations might be attended by an unnecessary amount of pain, or even cruelty; but these exceptional cases would not be of frequent occurrence. Government might exercise some control over the manner in which the experiments were performed; and even were this not done, wanton acts of cruelty are so inconsistent with the spirit of the times we live in, that, under whatever pretext they were committed, they would not be allowed to go long unpunished.

Even while we are penning these remarks the Royal Commission have issued their Report on Vivisection, and we are glad to see that, although recommending some such Government control as we have just suggested, they wholly repudiate the extravagant views and aims of the anti-vivisectionists. This precious society may therefore soon die a natural death, along with a petition to Parliament which is now going round for signature in various parts of London.

Notes on Current Topics.

Action of the Salts of Quinine.

THE action of the salts of quinine on the circulation has been the subject of many researches. In some these salts produce anæmia of the brain; in others merely diminution

of the reflex excitability of the vaso-motor system. Hammond distinguishes two periods in the action of sulphate of quinine; in the first, or period of active congestion, the arteries of the brain are hyperæmic; in the second, the period of passive congestion, there is eugorgement of the vessels. Hammond, after having had the state of his retina determined by the ophthalmoscope, took fifty grains of sulphate of quinine, and it was then found rhat his retina was more congested than before.

In three cases of photopsy from neuro-paralytic aperæmia M. Secondi obtained a complete and rapid cure by sulphate of quinine, and it is difficult to reconcile the cure in these cases with the facts of physiology. In fact one teaches that the disease is due to a lesion of the vaso-motor system, and the other indicates that quinine ought to produce a similar lesion, and nevertheless the disease is cured. There exist, then, on this question several obscure points to be cleared up. Either physiology must bring new facts to bear, or clinical study must modify the interpretation of symptoms.

"Patent Medicines."

THE death of a child from the effects of a "patent medicine" is by no means an unusual occurrence, yet, notwithstanding the frequently repeated warnings of coroners' juries, mothers still continue to dose their children with poisonous drugs, and scarcely a week passes without some case being recorded of a hapless baby falling a victim to this dangerous practice. An inquest has been held in Marylebone on the remains of a little girl aged six months, who, being ill from bronchitis, was given by its mother five doses of a patent medicine called "Infants' Preservative." As the child, instead of getting better, got worse, it was taken to a doctor, who pronounced it to have been poisoned, and it died the same afternoon. In giving his evidence to the jury the doctor complained of the protection afforded to vendors of quack medicines. "Had he" said the witness, "or any practitioner administered such medicine (as that given to the deceased child) they would have been held responsible. Yet under a patent and a Government stamp the vendor escaped." The medicine on being analysed was found to contain opium, and the jury returned a verdict that the deceased died from congestion of the lungs, accelerated by narcotic poisoning, the said narcotic being contained in a bottle of the "Infants' Preservative" administered to it.

Sanitary Condition of Hastings.

THE letter which we publish from a resident in Hastings is one which the Town Council may study with advantage, and looking to the commercial interests of the town, and the health of its inhabitants, they will do well to have the matter referred to by our correspondent thoroughly investigated. The inhabitants and the visitors of Hastings are indebted to anyone who will expose its imperfections, for not until they are made public will any attempt be made to remove them. On the best authority we have ascertained that sewage-polluted wells abound, and that the drainage of private houses is imperfect, whilst additional proof is added of the very imperfect water-supply. The story of bad drainage and the effect of sewer-gases is so well known, and is so often discussed, that we need scarcely now enter upon it, but the existence in the town of dangerous forms of drainage will be now made known to the authorities of Hastings, and they are bound to have them sought out and at once removed. It would be unnecessary to look further for a cause of the epidemics of diphtheria which Hastings has undergone, but we will again turn for a moment to the water.

On all sides it is acknowledged that the water-supply is insufficient, in fact, that the supply is not on long enough to fill the cisterns. What can the people do when they have no water in their cisterns? Their only resource is the nearest well. We are informed that sewage-polluted wells abound, and lodging-house keepers are not likely to know or care about the composition of the water so long as they can supply their visitors with water without much trouble. Unless water is supplied in sufficient quantity, sewage-polluted well-water will continue to be made use of both for drinking purposes and for the *adulteration of milk* (*a*), and we shall continually hear, as we do at the present time, of people who have returned from a visit to Hastings in ill health, and who have consequently decided never to go there again.

He who points out a fault is no enemy, and we can assure the authorities of Hastings that grave defects in the sanitation of the town having been made known, will now have to be rectified, and if they would desire to gain the confidence of the public in the healthful condition of the town they will the more readily do so by acknowledging the existence of those defects and straightway having them removed.

Criminal Lunatics in Ireland.

AT the monthly meeting of the Board of Governors of Ballinasloe Lunatic Asylum the following resolution was carried:—"That the resident physician having reported that many cases sent into the asylum under criminal committal appearing to him by no means dangerous, and likely to yield to treatment, the governors call the attention of the magistrates of the county to the number of these cases sent in as dangerous committal lunatics. They impress upon the magistrates what has, perhaps, escaped their notice, that many of these cases could have been sent in under the ordinary form of admission, which would enable the governors to make the relations of such patients contribute to their support, which they cannot do in cases sent in under warrant for criminal lunatics, and would enable them also to discharge such cases as have yielded to treatment without the difficulty that is very properly imposed in criminal committals. Unless the magistrates assist the governors in this, the governors cannot keep down the ever-increasing burden on the rate payers."

London Water Supply.

PROFESSOR FRANKLAND reports that the water supplied to the metropolis, drawn from the Thames during the past month, was inferior in quality to that delivered in the preceding month. The water of the Chelsea, Grand Junction, and Lambeth Companies was slightly

(*a*) We have good reason for advising that the water supply of the dairies should be at once inspected.

turbid from inefficient filtration, and contained moving organisms; the Chelsea Company's water also contained fungoid growths; while that supplied by the New River and East London Companies was of better quality, but only a degree or two above the freezing point. The Kent Company's water, drawn from deep wells, was of its usual good quality, and its temperature 18 degrees above freezing point. Major Bolton, the water examiner, warns householders against the condition of their cisterns which too frequently contaminate the water supply.

Meteorology in India in relation to Cholera.

At the meeting of the Meteorological Society of Great Britain, held on Wednesday last, a most interesting paper on the above important subject was read by Col. Puckle, M.S.C. In it the author mentioned certain facts in connection with several serious outbreaks of cholera in different parts of the Mysore country during the last fifteen years, and drew attention to the similarity of the abnormal meteorological conditions that existed on each occasion. Except in a few of the largest towns in India, there are no sewers, and no sewer-gas proper. Even in these exceptional towns the drainage is incomplete. The general sanitary arrangements are of the most primitive character. In the rural districts the inhabitants adhere to the Mosaic law in so far that they go forth to the fields, but they do not carry the "paddle" with them for the purpose that was the exponent of the "dry earth" system; *that* necessary portion of the work is left to the drying action of the powerful sun, to the kites and other carrion birds, and, *horribile dictu*, to the pigs and poultry that afterwards are doubtless turned into food. In this way it is not difficult to conceive that sewage of the direst and most unadulterated kind may possibly be taken into the system through poisoned meat, or during rainfall it may find its way to open reservoirs or wells, from which two sources the inhabitants depend for their water supply. At other times, during the hot, dry weather, when no rain falls, malaria may arise and be distributed through the agency of the atmosphere. Notwithstanding all that has been said and done, the clue to the mystery of the origin of the disease remains undiscovered. It is the same with the treatment; remedies that at one time appeared to be most effectual, at another most signally failed. Even during the same attack the same remedy that cured one person would fail in another, even when the same conditions apparently existed. Failure of the usual rainfall at the proper time, and abnormally high and harsh temperature, have been concurrent with several attacks in Mysore and Southern India. At such times the open reservoirs or lakes and wells are much below the usual spring level, and any contamination received at such a time is obviously much less diluted, and more harmful. Col. Puckle's account of several attacks that have come under his own personal knowledge coincides with that of other observers, shows beyond doubt that the disease has been arrested by change of air and surroundings, and that ordinary sanitary practice has prevented a possible outbreak. After referring to the recent outbreak at Bangalore and Madras, the author remarked that everywhere the same story is told of the occurrence of cholera coincident with long absence of rain and a temperature abnormally high.

Chloroforming an Insect.

In the *Archives Médicales Belges* is reported the case of a little girl who introduced an insect into her ear. As it was productive of the most intense pain, and even convulsive phenomena, it became necessary at once to remove it. Injections of water were made use of, but without result. Four drops of chloroform were then introduced into the ear upon a piece of cotton-wool, by which means the insect became asphyxiated, and was then readily washed out.

To Open an Abscess without Pain.

Dr. Bergonzini reports in the *Rivista Clin. di Bologna* that if the following solution be applied to the skin over an abscess for three to five minutes an incision may be made into it without pain: Carbolic acid, two parts; glycerine, one part.

The Origin of Syphilis.

The following quotation, sent us by Mr. Atcherley, is interesting, although not new. It will be found quoted in Lancereaux's great work, chap. ii. We do not think that syphilis was seen in Europe, as the paragraph might seem to suggest, before the discovery of America; and, although there is no time to go into the evidence, we hold that the disease was imported by the sailors of Columbus in 1493:—

Petri Martyris A.M. Epistolarum, Lib. I., Epis. LXVIII. —"In peculiarem te nostræ tempestatis morbum, qui appellatione Hispana Bubarum dicitur, ab Italis morbus Gallicus, medicorum Elephantiam alii, alii aliter appellant, incidisse præcipitem, libero ad me Scribis pede. Lugubri autem elogo calamitatem, ærumnasque gemis tuas, articulorum impedimentum, internodiorum hebetudinem, junctu-rarum omnium dolores intensos esse proclamas, ulcerum et oris fœditatem superadditam miseranda promis eloquentia, conquereris, lamentaris, deploras. . . . Vale. Giennio in nonis Aprilis, MCCCCLXXXVIII."

Admission of Women to the Medical Profession.

The date for the second reading of Mr. Cowper-Temple's Bill is fixed for the 5th of July. The object of the Bill is to gain the admission to the Register of women who may have taken certain foreign degrees. It is questionable whether Mr. Cowper-Temple has any expectation of his Bill being passed, but even if it should not be read it has served his purpose by keeping the matter before the House. We hear that the Duke of Richmond has expressed his willingness to receive a deputation from those who desire to see women occupy a position as members of the medical profession; so from the signs of the times we may expect the Government to take up the question, and in that case Mr. Cowper-Temple's Bill would probably be waived.

The Council of the College of Surgeons of England have sanctioned the admission of three ladies to the examination for the Licentiate in Midwifery, and doubtless the rules and regulations for the curriculum to be undergone by ladies desirous of presenting themselves for such examination will be shortly published.

Singing Bees.

A MOVEMENT is on foot in the metropolis to establish "Singing" as well as "Spelling" Bees, somewhat resembling the singing competition which has just taken place at Wellington Hall, Islington, where the members of the Barnsbury Literary Institute competed for prizes. On the occasion referred to a prize was awarded to the best male voice, and one to the best female voice. Some well-known professors of music are said to be arranging the preliminaries of the first "Singing" Bee in London.

Consumption of Horse Flesh.

THE horse-meat establishments in Paris delivered for consumption during the past year 6,865 horses, asses, or mules, which yielded 1,249,190 kilogrammes (2.2 lb. each)

Poisoning by Aconite.

THE *Echo* reports that on Tuesday last Dr. Turner, of Northampton, committed suicide by taking a dose of aconite. He had recently resigned the post of medical officer to the Friendly Societies' Institute, and had fallen intemperate habits. He had been in the habit of taking opium and other anodynes to induce sleep.

Toughened Glass.

WE some time ago noticed in these columns an invention, patented by M. Royer de la Bastie, by which the brittle nature of glass could be so changed that such ordinary articles as lamp glasses, watch glasses, glass plates and dishes, &c., would bear much rough usage and throwing about without breaking, and the patentee hoped to be able to apply his invention to glass goods of all kinds. The *Chemist and Druggist* says that the success which M. de la Bastie might have fairly anticipated has not run with him. Finding it difficult to induce glass manufacturers in this country to adopt his patent, he commenced in France in a small way the production, but by strange ill-fortune the premises he occupied were twice burnt down, and he is now in the third attempt, expecting in two or three months to supply the public. A London firm last year essayed to work the invention with an unsatisfactory result. The prices at which the firm could sell were prohibitory, and they have now relinquished any serious attempt to work the patent at all.

Irish Vaccination Grants.

WE print in another part of our issue an interesting, and to Irish readers an important, debate in the House of Commons, raised by Mr. Meldon, M.P., on the motion for supply. Mr. Meldon and many other Irish and Scotch members protested with earnestness and with good reason against the partial expenditure of the public money for purposes of vaccination., complaining that not only was the Chancellor of the Exchequer unable to afford more than £400 for vaccination service of Ireland while he granted £10,000 to England, but that Ireland was actually starved of her supply of lymph by the refusal of the English office to assist when urgently requested. The subject is one which cannot be dealt with in the limits which we are able to give it this week, but we shall return to it with our next issue, premising, meanwhile, that Mr. Meldon has good justification for his complaint, and deserves the best thanks of the profession for his action in the matter.

A Slight to Army Medical Officers.

NEARLY all the staff medical officers at present serving in Dublin, numbering about twenty, attended the levée of his Grace the Lord Lieutenant on the 1st inst. The first great Castle ball took place last week, and, as is usual, nearly every one of the landed, professional, and official classes who had been to the levée were invited to this entertainment. Of the Army Medical Department only the Surgeon-General and one other officer appeared to have received this usual courtesy. It may seem a small matter to Government officials to snub medical officers of the army in this way, but it will most assuredly produce most unpleasant consequences for the department. Last week we drew attention to the fact that for forty appointments only fourteen candidates presented themselves, and no competition was in consequence held. Do those who have the management of official receptions in our cities and garrison towns imagine that these continued slights are overlooked, or will be quietly submitted to? Their treatment in the past alone is the only cause of the paucity of men for the Army Medical Deparment, and we are proud to find that our young men have souls to resent in such a practical manner the insults officials are wont to heap on them.

Increase of Salaries to Resident Medical Superintendents of Irish District Asylums.

AT the meeting of the Omagh Governors last week, it was unanimously resolved that the salary of Dr. West, Resident Medical Superintendent of the co. Tyrone Asylum, be increased by the sum of 100*l.* per annum, under the 29th Privy Council Rule. This rule empowers the governors to add the above sum to the salaries of all such officers who have been eight years acting as Medical Superintendent, and should be invariably acted on where capital officers have given satisfaction to the local board. But we fail to see why the Privy Council should have restricted its just and wise provisions to the office of Resident Superintendent.

The Visiting Physician is as deserving of consideration for long and good service, and almost as essential to the good management of the asylum as the Resident, and yet we have heard that an increase of salary to one of their number, voted unanimously by the Board of Governors four or five times, was refused on each occasion by the authorities at Dublin Castle, and has only been recently conceded. Even when—as in the instance to which we allude—the duties of the Visiting Physician are doubled, the Castle authorities deny him any acknowledgment of his increased labours. By Rule 42 of the Privy Council Regulations (*see* Irish Med. Directory, page 268) the Visiting Physician who receives, say, 100*l.* a year for an attendance at the asylum three times a week is obliged, the moment that the number of patients passes 200, to attend every day, but there is no provision whatever—uch as is set down in the case of the Resident Officer—

for increased salary, and, as we have said, the voluntary vote of the Governors in his behalf is met with a veto when it reaches the inspectors. We are glad to see the Resident Medical Superintendent receive his just reward for long service, and only plead for "like cause like rule" in the case of the Visiting Physician.

Insurance Policies.

THE Whitechapel murder has given rise to a rather curious question of law. Henry Wainwright had insured his life, but had allowed the last annual payment due upon his policy to remain unpaid. After his conviction and sentence to death, his brother, who had paid the cost of his trial, went to the insurance office and demanded that the policy should be renewed upon the conditions for the renewal of lapsed policies named in the company's regulations. The brother produced a proper medical certificate declaring that Henry was in good health. The insurance officials were not a little puzzled, inasmuch as they had no provision, as some offices have, that policies are voided by suicide and by death at the hands of the executioner. So counsel's opinion was taken, and it was very decided that a man under sentence of death could not be considered an insurable life. Thus fortified, the company refused to renew the murderer's policy, and the 800*l.* was not forthcoming.

The Eagley Epidemic.

DURING the past week the officials of the Local Government Board have been actively employed in investigating the causes of this sad epidemic, so that we shall shortly be in possession of the actual facts. It appears, however, beyond doubt, that its origin was from the milk supplied at a neighbouring farm where the cows had drank water largely contaminated with sewage. Almost without exception the families attacked were supplied with this milk, and the result is obvious. The disease has unfortunately extended to Bolton from the same cause, over seventy having been attacked in that town, which, with the 120 in the village of Eagley, make nearly 200 at the time of going to press. Fortunately only seven or eight deaths have occurred; the remaining cases are doing favourably.

Advice to Mothers.

WHENEVER the daily papers announce the birth of an infant the mother is immediately informed where she can obtain the best and the cheapest baby-linen. But though the baby is the subject of consideration in the minds of so many philanthropic individuals, few people concern themselves about the mother.

Somebody—we don't know who, it may be a second-hand bookseller, or it may be Mr. Pye Chavasse—has determined that in future neither the mother nor the child shall be neglected; and accordingly a circular is now issued to the mothers of new-born babies, informing them that Mr. Pye Chavasse is the author of a work entitled "Advice to a Wife on the Management of her own Health," and of another work entitled "Advice to a Mother on the Management of her Children," and that a single copy of either book or of other works by the same author will be forwarded on the receipt of a post-office order.

Doubtless it is very kind and thoughtful of the writer of the circular to take so great an interest in lying-in women, but we would advise him that the ladies to whom it is sent have already medical advisers, and therefore do not require the work; but if any good is intended to be effected, a copy of the works should be sent gratuitously to the poorer class of people, who cannot afford to obtain the services of a medical man.

There is one other point that we must not omit to mention, namely, that the distribution of this circular will lower Mr. Pye Chavasse in the estimation of his professional brethren, and therefore, unless he wishes to be credited with its authorship and classed with the baby-linen advertisers, he had better prohibit its circulation.

Legislation on Irish County Infirmaries.

THE Bill of Mr. Edward Gibson, the Member for Dublin Universities, by which he intends to terminate the exclusive right of the Irish College of Surgeons to qualify surgeons for Irish County Infirmaries has not yet been laid onthe table of the House; it will be, we believe, straight to the point at which he aims. It will not, we imagine, be opposed by the Council of the College of Surgeons, who, we do them the credit to believe, have no desire to sustain a monopoly which could not be defended on legal ground, even although they may consider the right of the College to license surgeons still pre-eminent.

Mr. Meldon's Infirmary Bill is not yet printed, but its author, we believe, desires to remove the management of the infirmaries from the present Board of Governors, and to vest the same in a committee of Poor-law guardians, in addition to the life governors and annual subscribers. It is, we believe, also part of his programme to throw the public grants to these institutions upon the poor rates, and not, as heretofore, upon the grand jury cess. He will, we understand, ask Parliament to assent to the granting of superannuation allowances to infirmary surgeons. Until we see the Bill we must suspend our opinion, but, if we have judged accurately of its contents, we cannot be expected to express satisfaction at the proposal to "guardianize" the county infirmaries of Ireland. Heaven help them as surgical hospitals if they be placed under control of Poor-law guardians such as those whose doings and sayings we record every week!

THE *Chemist and Druggist* states that at St. Bartholomew's there is consumed during a year about seven hundred gallons of cod liver oil, eight hundred pounds of castor oil, and twelve hundred pounds of Epsom salts.

IT is announced that the Sultan has raised his medical attendant to a rank equivalent to that of a general of division, and has bestowed upon him a gift of 1,000 Turkish pounds as an acknowledgment of his services in successfully treating his Majesty for the carbuncle from which he was suffering.

AT the meeting of the Asylums Board on Saturday week it was reported that there had been an alarming in-

crease of typhus fever cases admitted to the Homerton Hospital during the past few days, the majority of them coming from the parish of Whitechapel. It was resolved to write to the Vestry of Whitechapel, drawing their attention to the matter, and asking that such steps shall be taken as shall tend to allay the danger.

THE next meeting of the Pharmaceutical Society of Great Britain will be held on next Wednesday evening, at eight o'clock. The following papers will be read :—"On the Preparation of Ferrous Phosphate of the British Pharmacopœia." By Mr. Rees Price. "Structure and Development of Pareira Stem (*Chondodendron tomentosum*, R. et P.)" By John Moss, F.C.S. "On the Degrees of Accuracy given by Druggists in the Dispensing of Physicians' Prescriptions in Different Towns in England and Scotland." By William Thomson, F.C.S.

Correspondence.

"HASTINGS WATER SUPPLY."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with great pleasure the outspoken remarks in the MEDICAL PRESS AND CIRCULAR on the Hastings water supply, and when Mr. Cogswell says that it is evident the facts relative to that supply are very imperfectly known to you, I must reply that in that case you only erred on the side of leniency.

I must confess that I am puzzled by hearing that £41,500 has been borrowed, or applied for, during the last twelve months for water purposes, and others to whom I have appealed for information are equally mystified.

However, the sum is not of much moment; what is of more importance is, how it is spent. If £41,500 really has been borrowed, it is a great pity that it should be expended on mere temporising schemes.

Mr. Cogswell states that the Town Council have expressed their desire to give us a constant service. I can only say that, on the contrary, their "mouthpieces" have of late told us positively that the expense is too great.

Mr. Cogswell knows too, as well as anybody, that the promises of Town Councils not unfrequently share the fate which is supposed to fall to the lot of other "good intentions"; but when we are informed that "it is intended to make a *partial trial* of the system *as soon as the means to do so exist*," it is impossible to avoid admiring the guarded nature of the expression conveyed by the words which I have italicised.

It is evident that just as a man who wishes to pay his creditors must first "raise the wind," so before the Council can supply us with a constant service they must raise the water. But I shall show that, as far as *water* is concerned, this town is in a state of bankruptcy.

Mr. Cogswell justly terms Mr. Topley's a valuable report, and I entirely agree with him; when, however, he says that his recommendations are "*as far as practicable*, being acted upon," I must differ, and suggest as a truer reading, "*as far as agreeable*"; for, to put another simile, our Council finds itself in the position of a man who consults his doctor, but finds his advice unpalatable.

Now, I find the total supply of Hastings and St. Leonard's in 1874 estimated at 578,000 gallons daily. The population in 1871 was 33,000. This gives us only 17·5 gallons per head daily—a most inadequate quantity. 1874 was a very dry year, but, just as the strength of a chain is that of its weakest link, so we must test a water-sourse by unfavourable years in order to discover its real value.

To return, of these 578,000 gallons, a large proportion proves to be surface-water of an objectionable kind; Mr. Topley therefore justly condemns at least 88,351 gallons—the old Roar and two other reservoirs. If we deduct these suspicious sources we find the supply in a bad year would sink to something like 13 gallons per head daily—an amount far short of what is necessary for cleanliness and health. Nor is it probable that augmentation of the supply from the present works, &c., will do much more than balance the loss of that which will have to be abandoned, if we are to be supplied with pure water.

Thus it appears that the present fund of water is insufficient to meet the wants of the *present* population. No wonder, then, that the water is laid on for such brief periods, that some houses are often supplied but three days in the week, that people, finding their cisterns empty, drink the water of the excrement-polluted wells that abound, and that scarcity every now and then becomes a famine.

But it has been estimated that Hastings is growing at the rate of 200 houses per annum. Next year, too, an aquarium will be opened, and probably increased railway accommodation will be afforded, which will certainly not check the influx of population.

Mr. Topley considers it wise to provide for 50,000 inhabitants at 30 gallons a head daily = 1,500,000 gallons.

It is ridiculous to think that a supply, which is by 400,000 gallons a day too small for the present, will suffice for the population of a few years to come.

The plain truth is that water must be brought from a distance, and the Town Council are afraid of the expense.

There is in every town a large body of ratepayers, ignorant of the laws of cleanliness and health, to whom the prime virtue in a councillor is to lower the rates, and, in places like Hastings, there is another body who are so jealous of the sanitary reputation of their town, that rather than create the noise which they fancy a reform would entail, they hush up nuisances and (metaphorically) stifle the would-be reformer.

I contend, then, that to argue with the Council for a constant service is waste of time, for they are not at present in a position to give us a proper supply of any sort.

The final sentence of your correspondent's letter is devoid of logical sequence, and not borne out by facts.

Apologising for trespassing so far upon your space, I enclose my card, and

Remain, Sir, your obedient servant,

St. Leonard's Club, M.D.
Feb. 17, 1876.

THE MEDICAL INSPECTORSHIP.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your surmise as to the probable appointment to be made to the now vacant Medical Inspectorship ought certainly to arouse the Medical Corporation to try and secure what ought to be recognised as a prize for dispensary medical officers. What is our representative body—the Council of the Irish Medical Association—now doing? Why not immediately send a deputation to the powers that be, and make known the wishes of the profession?

DISPENSARIUS.

P.S.—Is there not a second Inspectorship vacant, by the promotion of Captain Robinson, or has it been already disposed of?

[The Council of the Irish Medical Association is vigilant and prepared to act when they have reason to consider that circumstances require. Our correspondent will observe from our observations elsewhere that the emergency does not at present arise. Mr. Robinson's vacancy has been already filled by the appointment of Mr. Armstrong.—ED. M. P. & C.]

A BILL TO AMEND THE MEDICAL ACT, 1858,

SO FAR AS RELATES TO THE REGISTRATION OF WOMEN WHO HAVE TAKEN THE DEGREE OF DOCTOR OF MEDICINE IN A FOREIGN UNIVERSITY.

WHEREAS under the provisions of the Medical Act, 1858, a woman who had taken the degree of doctor of medicine in a foreign or colonial university, and had practised as a physician in the United Kingdom before the passing of the Act, was qualified to be registered:

And whereas it is expedient that any woman who possesses the degree of doctor of medicine of a foreign university may be entitled to be registered, although she has not practised as a physician in the United Kingdom before the first day of October, 1858.

Be it therefore enacted, &c., &c.

1. Every woman to whom the degree of doctor of medicine has been or may hereafter be granted, after regular examination, by any of the foreign universities mentioned in the schedule to this Act, shall, upon application to that effect, be entitled to be registered in the terms of section fifteen of the Medical Act, and on the same conditions as are laid down in sections twenty and twenty-one of the said Act, as applicable to degrees granted by the examining colleges and bodies of the United Kingdom.

2. It shall be lawful from time to time for the General Medical Council to add other foreign or colonial universities to those mentioned in the schedule to this Act, and whenever the said Council shall have determined and issued an order to that effect, the degree of doctor of medicine of such university or universities shall thereupon constitute a qualification entitling any woman holding the same to registration under the Medical Act, 1858, subject always to the conditions mentioned in the above-mentioned sections of the said Act.

3. This Act may be cited for all purposes as the Medical Act (Foreign Universities), 1876, and shall be construed as one with the Medical Acts.

SCHEDULE.

Universities of France, Berlin, Vienna, Leipsig, Berne, and Zurich.

WESTON'S FORTY-EIGHT HOURS' WALK.

Report by J. ASHBURTON THOMPSON, L.R.C.P., &c.

A DESCRIPTION of the physique of a man endowed with the extraordinary powers of endurance shown by Edward Payson Weston, the American long-distance pedestrian, offers many points of interest. He is a tall, slight, and very thin man. His head, hands, and feet are small; his limbs, though well-knit and shapely, are spare. He is remarkably wide in the hips, the pelvis somewhat resembling that of the female, and in consequence his thighs are widely separated. He is of a highly nervous temperament; his expression denotes the possession of that quality which is sometimes called firmness and sometimes obstinacy; but in conversation his expression is extremely pleasant and amiable. He is vivacious, but easily depressed; courteous, but (on these occasions at least) irritable. A man of education, and some time a writer for the press of his own country, an easy flow of words, felicity of expression, and a marked sense of humour, combine with his sincerity of manner to produce an effect which will ensure him something more than the passing popularity which his feats command. Nothing illustrates his nervous impressibility better than an observation of the marked effect produced by a cheerful word of encouragement offered at times when he is fatigued; his face, evidently unconsciously, improves at once. So, too, when the monotony of the walk became oppressive, he will call upon the band to play one of certain favourite tunes; and under its inspiring influence he saves a minute on the time of the mile. To the wideness of the hips is no doubt in part owing his peculiar gait. At each step the body receives a slight jerk, which at times of fatigue becomes almost a swagger. The knees are kept constantly flexed at a slight angle; very little movement of the joint can be observed; in consequence the foot is planted firmly and rather flat, and there is very little spring in his walk. But his progression is constant; there is none of the pause which may be observed between each step in ordinary walkers; and on getting a little accustomed to his appearance it becomes plain that his method is eminently serviceable in getting over the ground. The arms are allowed to swing and are unflexed, in this point differing from English fast walkers, who usually flex the forearm to a right angle; but he does not swing the arm more than they. He does not appear to fix the thorax, which moves freely; but he held it more steady, and in every respect walked in better form than upon the last occasion. His clothing calls for no particular notice; his boots being of the kind usually selected for walking tours by amateur pedestrians—viz., laced Balmorals, as wide at the toes as at the other parts of the sole.

During a walk he takes frequent rests, at first at short intervals, and then, as the period of exertion becomes longer, at longer intervals; and whereas in the earlier part of the journey his period of rest is governed chiefly by the time which he has to spare, later on he is careful not to prolong it, theoretically because the limbs are then liable to become stiff. Practically, upon this occasion, he made little difference in the length of his rest. At the end of each twenty-four hours he takes two hours of sleep, and it is only during this interval that he uses any solid food. He generally takes cold beef, not exceeding four ounces; but he does not appear certain that it is of benefit to him, and sometimes feels sick after it. He depends for support upon Liebig's extract and calves'-foot jelly, and he drinks a great deal of tea to keep off sleep, but which, no doubt, answers other purposes as well. To these he adds lemons, oranges, grapes, and occasionally ice. He takes his fluids cold, as a rule; but when he feels the need of a stimulant, he uses them very hot. He is not a total abstainer, but while training he abjures tobacco and alcohol (the quantities of which usually allowed are very small). During a journey he never takes any alcoholic drink, special reasons having led him to break through this custom on the last occasion.

Weston began his undertaking to cover 180 miles in 24 hours on the 15th inst., at 9.45 p.m. The following thermometrical observations were taken in the mouth, either while walking or resting as specified. The instrument was supplied by Messrs. Negretti and Zambra, and was duly certified. It was first of all ascertained that an exposure of one minute was sufficient to attain a maximum temperature. A much longer exposure was used, however, upon these occasions, and care was taken to avoid such errors as might arise from the temperaure of the fluid last taken. His temperature at starting was ascertained to be 99·2. At 3 a.m., 16th inst., he was doing the 26th mile. Time of last mile, 12m. 50s.; T. 98·1 (exposure, 1m. 50s.) His face was at this time rather pale, and his expression anxious. The track was in an abominable condition, the feet slipping at each step, and the work was evidently very hard. He complained of the right hip, which he said was strained in consequence, and he had lost his stomach, being unable to take his usual nourishment. He fought on with indomitable perseverance, however (for he was obliged to walk in as good time as he would have done had the track been perfect), until 7.30 a.m., when he repaired to a bed prepared by the course. It was so arranged that the feet and head were both raised. His legs and arms were uncovered, and the limbs rubbed upwards with bay-rum; his face, head, and hands were sponged with toilet vinegar. After brushing his hair and pouring whisky into his boots by means of a funnel he started off again, having rested 11m. 30s. At 9.8 a.m. he rested again. At 9.45 he was going well over the fifty-fifth mile; he appeared cheerful; T. 97.4 (exposure 1m. 45s.). He complained much of the state of the stomach. He was unwilling to talk much; but as far as I could understand, his discomfort arose from a sensation of emptiness. I, therefore, agreeing that solid food was undesirable, recommended him to take some thick oatmeal gruel made with milk. Accordingly at 11h. 30m. a.m. he rested again 14m. 45s. The same processes were gone through as before. After 5m. rest, T. 97 (exposure 2m.); P. 98, steady, and of fair quality. He took almost half-a-pint of the gruel with a few biscuits in it, and started again. At 1.44 p.m. he rested again. At 4 p.m. he was looking fagged, pale, and anxious, but was travelling well (83rd mile), T. 97·1 (exposure, 1m. 45s.) At 4.27 p.m. he stopped 17m. 45s.; at 6.58, 7m. 47s.; and at 8.34 p.m. he rested for 23m. 20s.; 9 p.m., 6m. 35s. respectively. He was much fatigued, attributing his distress entirely to the hard work which the state of the track had entailed upon him. At the end of twenty-four hours he had covered 100 miles and two laps. His

spirits appeared good. After walking two laps more he rested. He was suffering from shock. His face was quite pale, his pulse 90, large, compressible, and irregular; his voice weak, and the surface cold; his temperature after 3m. exposure appeared to be 96 only. This was so low that the observation was corrected with another thermometer, which only indicated about a fifth of a degree more. He again took about half-a-pint of gruel very hot, and after staying 10m. 38s. he resumed work, apparently quite recovered. He made his average time, and to relieve the exuberance of his spirits, at the end of the 103rd mile he took occasion to walk about 100 yards backwards. About 11.30 p.m. he retired for his usual sleep of two hours. Another hour was occupied in dressing, &c., and he did not appear until 3.40 a.m. 18th inst. During this interval he had taken about 4oz. of cold beef, which he said made him feel sick; he did not vomit. The track was now perfect, and at 4 a.m. he was making good time in excellent form. T. 97·8 (exposure 2m.) Towards 5 a.m. he began to feel sleepy, and soon took a bath, with the desired effect of resting himself. At 8.55 a.m. he rested again. At 9.45 a.m. he appeared perfectly fresh, and indeed looked much better than at any period of the previous twenty-four hours. He conversed freely, read his correspondence, cut jokes with the audience, and on the whole appeared to be rather enjoying himself than performing an unprecedented feat; at the same time he was making the mile in about 13m. 30sec. T. 97 (exposure 1.55m.). He was now perfectly easy as to performing his task, for he had reduced it to a "four-mile-an-hour job," as he said, excluding rests; and it then appeared that he had been much troubled at only making a little over a hundred miles in the first day. He thought he should have done a hundred and ten. He rested at 12.5 p.m. At 2 p.m. he was looking a little fagged, but still making his average time; T. 97.1 (exposure 2 m.). At 2.40 p.m. he rested 9m. 27s. His pulse was 80, full, firm, and regular. He objected to my taking his temperature at this time. He rested again at 4.45 p.m. and 7.40 p.m., and from that time to the end he continued without stopping, and completed the 180th mile with 5m. 42s. to spare. He looked actually as fresh as ever, and there appeared to be no reason why he should not have done as he proposes on the 22nd inst.—walk another 24 hours. On going to the scales he was found to have lost 4¾ lbs. He then retired to his rooms, where he reclined on a sofa. His feet were bathed in warm salt and water. At first his pulse was high—102; but it soon began to fall, and after fifty-five minutes stood at 80. At the same time, T. 97·6. He appeared not in the least exhausted, and was left sleeping. He always vomits after a walk, and the first stool is always black; but he was very much hurt at the suggestion made in a contemporary that the evacuated matters contained altered blood. He said that he always made himself vomit in order to relieve his stomach of the tea which he has taken; otherwise it would not be in good condition next morning.

The utility of such an exhibition has been questioned. It is the recollection of such feats—of such *possibilities*—which stimulates men to perform tasks in moments of emergency which they would otherwise fail in, or even regard as hopeless and not attempt.

Parliamentary Intelligence.

HOUSE OF COMMONS.

VACCINATION ESTIMATES FOR ENGLAND, IRELAND, AND SCOTLAND.

On the question that £693,287 be voted for the expenses of the Local Government Board, including a charge for pauper lunatics,

Mr. Meldon moved that the vote be reduced by £1000. For vaccination purposes, £10,000 was voted to England, while the only State grant of the kind given to Ireland was £400. But the smallness of the sum did not show the extent of the grievance. Up to 1871 Ireland was supplied to a great extent with lymph through a cow-pock institution in that country, and a greater supply could be obtained if thought desirable from England. In 1871, for some unexplained cause, it seemed good to the Privy Council to change the system in Ireland, and they stopped all supplies of vaccine lymph to Ireland. The cow-pock institution in Ireland could not supply the whole country, and the Government offered to supply vaccine lymph if the institution would reduce the charge from 2s. 6d. to 6d. The cow-pock institution complained of the conduct of the Privy Council. He did not grudge any necessary vote for England, but he was compelled by the forms of the house to resort to this expedient for justice.

Mr. M'Laren asked the Government to postpone the vote until after a Scotch deputation had waited upon the Chancellor of the Exchequer.

Mr. Sclater-Booth said that if the hon. gentleman (Mr. Meldon) would give him full information he (Mr. Sclater-Booth) would inquire into the case. He desired to inform the last speaker that any arrangements which the Chancellor of the Exchequer might make with reference to Scotland would not affect this vote.

Captain Nolan had no desire to diminish vaccination in England, and he should be very sorry to do so, but this seemed to be the only form in which the grievance could be brought forward. If £10,000 was voted to England, Ireland, where small-pox had been very rife, was surely entitled to a grant of more than £400.

Sir M. H. Beach said that he would inform himself more fully upon the matter, the importance of which he fully acknowledged, if the hon. gentleman would call attention to the subject again.

M. M'Laren complained that, in a vote of £24,900 for vaccination purposes, Scotland had an allowance of only £500, and under such circumstances he should object to the vote. There were other items also which needed explanation.

Dr. Ward suggested that the Government should do something to facilitate the supply of free vaccine lymph to Ireland. It was remarkable that in 1871, when the supply of free vaccine lymph was stopped, there should be immediately afterwards a most severe outbreak of small-pox in Ireland.

Mr. W. H. Smith said none of the charges in the vote were new, and to lessen the amount would not remedy any deficiency of lymph in Ireland.

Mr. Meldon rejoined that if the Government did not consent to postpone this vote he should divide the committee upon it.

Lord R. Montagu explained the system of premiums to the official vaccinators, under which vaccination was carried out in England.

Mr. Waddy could not understand how knocking off the lymph for England would get it for Ireland. (Hear.)

The Chancellor of the Exchequer said that what was proposed for England had always been done in England, and whether the Scotch vote should be brought up to that level was a different question.

Mr. Muntz denied that disease was propagated by vaccination, although that fact was insisted upon by a noisy faction all over the country. (Hear, hear.)

Mr. J. Barclay moved that the Chairman report progress.

The Chancellor of the Exchequer did not see how the postponement of this vote would assist the object of the Scotch members.

Captain Nolan said that the question was why there should be six times as much per head voted for vaccination in England as there was in Ireland.

Mr. Dillwyn would gladly support a motion for an increase of grant for Scotland or Ireland; but he could not consent to the reduction of this vote.

Mr. Sclater-Booth explained that the present vote had been really agreed to for years; the various items of it sprung out of acts of Parliament which were still in force.

Dr. Cameron hoped that the Government would accede to there being one uniform system for the three countries.

Mr. Sclater-Booth thought that this vote ought to be agreed to on its merits, and the other matters discussed on a subsequent occasion.

Mr. J. Barclay withdrew his amendment.

Mr. Whitwell asked whether £333,000 was about the amount likely to be required for the support of pauper lunatics.

Mr. Sclater-Booth said that the £330,000 voted last year had, with the exception of a very small fraction, been expended, and it was expected that somewhat more would be required for this year.

The amendment was then withdrawn, and the vote was agreed to.

CIVILIAN MEDICAL MEN.

Mr. Ward—I beg to ask the Secretary of State for War how many civilian medical men are at present employed in the United Kingdom doing duty with troops.

Mr. Hardy, in reply to the hon. member's question—I have to state that the number of civilian medical men at present employed in the army is 41, in addition to several who are employed temporarily during the absence on leave of the regular medical men. Several civilian medical men are also employed in the auxiliary forces on special occasions.

Obituary.

SIR DUNCAN GIBB, M.D.

We have to announce the death of this gentleman, at the early age of 54. He has been ailing for some time past, and had resigned the Physiciancy of the Westminster Hospital in consequence. Originally a St. Bartholomew's Hospital Student, he migrated to Canada, and graduated at McGill College, Montreal, in 1846. He was M.R.C.P. of London, L.R.C.S. Ireland, &c., and the author of "Diseases of the Throat and Windpipe," "The Laryngoscope in Throat Diseases," and other minor works and papers in the medical journals.

DOCTOR O'ROURKE, OF ENNISCORTHY.

We sincerely regret the demise of Dr. O'Rourke, which took place at his residence, Enniscorthy, on the 9th inst., at the patriarchal age of 80 years. Dr. O'Rourke was a native of Carrick-on-Suir, and in early life became a resident of Enniscorthy, where he enjoyed not only a very large practice in his profession, but the confidence and esteem of all classes of that community, more especially the poor, to whom he was a generous benefactor and friend. As a politician the learned doctor was an ardent lover of his country—a genuine Liberal of the O'Connell school, in which he held a foremost position for over half a century. He was medical officer of the Enniscorthy Union for several years, as also chairman of the Town Commissioners. Dr. O'Rourke was a staunch friend of his professional brethren, and by pen and voice never failed to aid them in any movement which deserved his support. For a great many years he was a friend and adviser of the Medical Press as to its Irish Poor-law medical function, but being an ardent Nationalist, withdrew his support upon the establishment of a large English connection for the journal. Nevertheless we have always known him as a man of considerable talent and of sterling principle, and the regret evinced in his own locality at his death shows that his social qualities were equally respected.

Death Certificates.—Yesterday in the House of Commons a question of considerable moment to the profession and the public was put by Mr. Waddy to the Government, in reply to which Mr. Sclater-Booth said that he had occasion to consider the question in 1874. According to the Registrar-General's report, many certificates were received from *unqualified* medical practitioners; but the Government were not prepared to say that certificates in cases of ordinary deaths from such persons should not be recognised. We are both surprised and shocked with the expression of such views by a cabinet minister; it is a matter of such vital importance that it cannot be allowed to rest there.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Several letters are unavoidably crowded out for want of space.

Mr. Atcherley is thanked; he will find the subject referred to in another column.

PYROSIS.

To the Editor of the Medical Press and Circular.

Sir,—If your correspondent has not already tried a mixture of the mineral and vegetable acids, I think he will find them useful in his case: hydrochloric and citric acids, pepsine wine and tincture of orange-peel, three times a day; or a mixture composed of hydrochloric acid, tincture ferri perchlor., and chloroform, has been very serviceable in the hands of

Yours, &c.,
J. H.

Dr. Greene.—Your "Contributions to the History of Puerperal Fever" will appear in an early number.

Royal College of Surgeons of England.—On Wednesday and Friday, at 4 p.m., Prof. Flower will continue his lectures "On the Relation of Extinct to Existing Mammalia."

Hunterian Society.—This evening, at 8 p.m., Dr. Langdon Downe, "On the Causes of Idiocy."

"OUR NEW NURSE."

To the Editor of the Medical Press and Circular.

"OUR NEW NURSE.—Should any of the children be unwell (symptoms, vomiting and diarrhœa), COMMUNICATE with —— and ——, Private Inquiry Office."

Sir,—The foregoing lately appeared in a contemporary, and appears to me to merit the designation of "scandalous."

It seems intended (I hope I am mistaken in so supposing) to suggest to anxious parents that the "new nurse," whose arrival has coincided with an attack of "vomiting and diarrhœa" on the part of her little charges, is possibly criminally responsible for the same! "Communicate with Messrs. ———, Private Inquiry Office," and let those worthies earn disreputable fees by putting on the rack the "new nurse" whose misfortune it has been to have to attend during her first week of service to a nursery of bilious children.

It is possible that a particular case only is here referred to. If so, it ought to have been indicated. As it appears, it is likely, whether intended or not, to sow in scores of families undeserved suspicion of the "new nurse."

T. B. G.

[We had observed the announcement referred to by our correspondent on its first appearance, but its insertion in "The Agony Column" of the paper led us to the belief that it was a signal or message for some particular person who alone would understand its true meaning, not an attack upon that useful body of women our *confrère* comes forward in honour and fairness to defend. And her correspondent has suggested, with a certain show of reason, that the mysterious announcement is probably a prelude to the ushering into the market of another soothing syrup (slow poison) for infants.—Ed. M. P. & C.]

Queekett Microscopical Club.—On Friday, at 8 p.m., Mr. R. Packenham Williams, "On an Improved Freezing Microtome." Mr. N. E. Green, "On a New Stage Arrangement for the Examination of Objects by Reflected or Transmitted Light."

Dr. W. H. G.—We are much pressed for space, and regret that insertion of your communication and those of other authors has been delayed.

Clinical Society of London.—On Friday, at 8½ p.m., Dr. Dyce Duckworth will exhibit a Patient with Morphœa. Dr. Moxon, "On two Cases of Leukæmia, one simple, one with Jaundice, neither with notable Enlargement of the Spleen; both treated with Phosphorus, and both dying by Hæmorrhage." Dr. Duffin, "On a case of Menière's Disease." Mr. Maunder, "On a successful Case of Gastro-enterotomy in a Male aged sixty-eight."

Communications, Enclosures, &c., have been received from—Mr. Bromley, Southampton. Dr. Van der Smagt, Ceylon. Dr. Satchell, Kew. The Director-General of the Army Medical Department. Mr. Alfred Haviland, Northampton. Dr. Downes, Hastings. Dr. Myrtle, Harrogate. Mr. Grace, Bristol. Dr. Dolan, Halifax. The Registrar-General. Mr. Tillotson, Bolton. Alton Hatchard, St. Leonard's-on-Sea. Dr. McNab, Epping. Prof. Mapother, Dublin. Dr. Harvey Hilliard, Holloway. Dr. Handsel Griffiths, Dublin. Mr. Jabez Hogg, London. Dr. Billing, London. Dr. Landon, Richmond, Virginia. Mr. Wilder, Reading. Mr. Weston, London. Dr. J. C. Mackenzie, Cincinnati, Ohio, &c., &c.

VACANCIES.

City of London Hospital, Victoria Park.—Assistant Physician. Honorary Physician. (See Advt.)

Lincoln Lunatic Hospital.—Resident Medical Superintendent. Salary £150, with board and residence. (See Advt.)

University of Durham College of Medicine.—A joint Lecturer on Anatomy and a Medical Tutor. Salary of the latter, £200. Full information of Dr. Bramwell.

North London Consumption Hospital.—Physician. Honorary. (See Advt.)

Northampton County Lunatic Asylum.—Medical Superintendent. Salary, £500, with residence, &c. Applications to the Clerk of the Peace, County Hall, Northampton.

Lisnaskea Union.—Medical Officer Brookeborough Dispensary District. Salary, £115, with £15 extra as Sanitary Officer. (See Advt.)

Manchester Clinical Hospital for Children.—House Surgeon. Salary, £80 per annum. Address the Secretary of the Medical Board.

University of Glasgow.—Examiners in Medicine. Applications to be lodged with Mr. Kirkwood, 166 West George Street, Glasgow.

Macclesfield General Infirmary.—House Surgeon. Salary. £120, with board and apartments. Applications to the Clerk at the Infirmary.

Nottingham Dispensary.—Assistant Resident Sorgeon. Salary, £170. Applications, with testimonials, to the Committee at the Dispensary.

Stamford Infirmary.—House Surgeon. Salary, £100, with board, &c. Address the Chairman of the Managing Committee.

Marriages.

BOOTH—HETHORN.—On the 10th inst, at the Parish Church, Bowdon, Lionel Booth, M.D., Accrington, Lancashire, to Frances Mary, eldest daughter of John Hethorn, Esq., Altrincham, Cheshire.

MERRICK—DAWSON.—On the 15th inst., at Kilkenny West, Alexander Stewart Merrick, M.D., Belfast, to Annie Elizabeth Frances, youngest daughter of Wm. Dawson, Esq., J.P., Nohaville, co. Westmeath.

Deaths.

ARBUCKLE.—On the 15th Feb., at Balmar, Kirkcudbright, William Arbuckle, M.D., Inspector-General of Hospitals Bombay Service, aged 67.

CANTRELL.—On the 7th Feb., at Middleton, Derbyshire, Wm. Cantrell, L.R.C.P Ed., aged 75.

CAREY.—On the 3rd Feb., at Edinburgh, Ernest G. Carey, M.B.

COLEMAN.—On the 10th Feb., at Galway, of congestion of the lungs, James J. Coleman, L.R.C.P.E., L.R.C.S.Ed.

COOKSON.—On the 7th Feb., A. D. Cookson, M.R.C.S.E, of Gloucester, aged 62.

DALE.—On the 10th Feb., at Regent's Park Terrace, Edmund Dale, M.D., of Wavertree, near Liverpool, and Holborn Hill, London, aged 73.

DEANE.—On the 10th Feb., at St. Ives, Hunts, James Deane, M.A., M.D, aged 63.

GREENE.—On the 6th Feb., at Sedgeley Park, John Greene, M.R.C.S.E., of Muxton, aged 67.

ILIFF.—On the 17th Feb. at Epsom, after a long illness, Wm. Tiffin Iliff, M.D., formerly of Newington, Surrey, aged 77.

IRVINE.—On the 18th Feb., at Eglinton Lodge, Irvinestown, Michael Robert, second son of Dr. Alexander Irvine, aged 14, deeply regretted.

JOSEPH.—On the 6th Feb., at Tipton, C. E. Joseph, M.R.C.S.E., aged 52.

TURNER.—On the 4th Feb., at Manningham, R. H. Turner, L.R.C.S.Ed., aged 37.

WAYMOUTH.—On the 17th Feb., at Lichfield, Albert Waymouth, M.R.C.S., aged 32.

WELCH.—On the 17th Feb., at 7 Powis Gardens, Kensington Park, W., Frances, relict of Dr. James Andrew Welch, of Dalston.

STROMEYER TESTIMONIAL.

AT an INFLUENTIAL MEETING, held on FEB. 14th, at 18 Park Street, Grosvenor Square, W., to consider the propriety of joining in the movement now going on in Germany to celebrate, on April 6th, the Fiftieth Anniversary of Stromeyer's admission to the Doctorate of Göttingen, it was unanimously agreed that an Address congratulating Stromeyer on his useful and honourable professional career be presented to him, as shown by his discovery of the safety and value of subcutaneous surgery, by the elevated tone of his surgical writings, and his successful efforts to improve the principles and details both of Military and Civil Surgery, as well as Military Hygiene. It was also resolved that Dr. Stromeyer be asked to sit for his Bust, which it is expected will find an honourable reception in England, and that a subscription list—no subscription to exceed two guineas—be opened for the purpose of carrying out the above object.

It was also resolved:—"That W. J. LITTLE, M.D., 18 Park Street, Grosvenor Square, W., and WILLIAM MACCORMAC, F.R.C.S., 13 Harley Street, W., do act as Joint Treasurers and Secretaries, to whom it is requested all communications may be addressed."

SUBSCRIPTIONS ALREADY RECEIVED.

ASSISTANT PHYSICIAN.—CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK, E.

A VACANCY having being created by the resignation of Dr. Sutton, one of the Physicians to the Institution, and the appointment of Dr. Shepherd, the Senior Assistant Physician, to succeed him, Candidates for the appointment of Assistant Physician are requested to send their applications, addressed to the Treasurer, on or before Saturday, the 26th inst. Information may be obtained of the Medical Officers or of the Secretary.

WILLIAM JONES, Secretary.

Office, 24 Finsbury Circus, E.C.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

TO SURGEON-DENTISTS.—TO BE LET, a First-class HOUSE, in the best part of DUBLIN, in which a large PRACTICE has been carried on for the last forty years, and until the last few days. For particulars address A. B., Dublin Office of this Journal, 23 Ely Place.

A VACANCY has occurred in the office of PHYSICIAN to the North London Consumption Hospital, London and Hampstead, by the resignation of Dr. W. Lomas. Candidates (who must be Members or Fellows of the College of Physicians, and Graduates in Medicine of a University) are requested to send their testimonials to the SECRETARY, on or before 1st March.

Office, 216 Tottenham Court Road, W.

MALVERN COLLEGE.

This COLLEGE contains THREE DEPARTMENTS—the CLASSICAL, MODERN, and PREPARATORY LOWER SCHOOL.

Boarding and Tuition under 14, £80; over 14, £90. Non-Shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information, apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

LINCOLN LUNATIC HOSPITAL.

WANTED a RESIDENT MEDICAL SUPERINTENDENT, who must be a duly registered general practitioner, holding at least two qualifications, one in Surgery and one in Medicine, unmarried, and free from burden of children. Salary, £150 per annum, with board, lodging, and washing. Applications, stating Age and Qualifications, accompanied by Testimonials, to be addressed to the Governors of the Lincoln Lunatic Hospital, under cover to the Secretary, Mr. Richard Hall, 38 Silver Street, Lincoln, not later than Saturday, the 11th day of March, 1876. The election will take place on Thursday, the 16th March, 1876.

By order of the Board,
RICHARD HALL, Secretary.

LISNASKEA UNION.

BROOKEBOROUGH DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—In consequence of the lamented death of their Medical Officer, Dr. Wilson, the Committee of Management of the above Dispensary District will, at their Meeting to be held on TUESDAY, 21st MARCH, 1876, at the hour of 12 o'Clock noon, proceed to elect a duly-qualified Medical and Sanitary Officer for the District, at a salary of £115 per annum as Medical Officer, and £15 per annum as Sanitary Officer, together with fees for Registration and Vaccination.

Applications for the Office, with Diplomas and Testimonials, will be received by the Assistant Honorary Secretary, "James Sproul, Esq., Skeage, Brookeborough."

Personal attendance of Candidates will be required on the day of Election.—By order,

J. O'R. HOEY, Clerk of Union.

25th January, 1876.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

IRISH POOR-LAW INTELLIGENCE.

THE EXPENSES OF SANITARY OFFICERS AT PETTY SESSIONS COURT.

THE Local Government Board, in reply to a letter of inquiry from the Drogheda Union, as to the legality of a fee of £1 granted to Dr. Drew, M.D., as sanitary officer for Termonfeckin, County Louth, by the magistrates on the hearing of a sanitary case which the doctor had reported in his official capacity, state that it is not one of the prescribed duties of the sanitary officer to attend at petty sessions to prosecute in such cases, and the question of costs is one for the magistrates to consider. Such being the case the sanitary officer, as a professional man, can fairly claim costs in every case.

Since this decision was given the question has been submitted to legal authority, at the County Watertord Petty Sessions, where a man was charged at the suit of the Clonmel Board of Guardians with depositing manure, of a quality dangerous to health, on the roadway at Glebe-lane, Old Bridge, and which he persisted in keeping there when noticed to have it removed.

When the case was called, Mr. O'Donohoe, solicitor, said that he appeared professionally for Dr. Scully, jun., in his capacity as Hon. Secretary to the County Tipperary Medical Protective Association, to request from the magistrates an order to have Dr. Scully paid £1 for his services and loss of time in attending the court. The object of the application was not so much the question of the £1, as to have the matter tested as to whether it was the duty of a sanitary officer to attend on such occasions, or whether he was entitled to be feed by the Board under the clause in the Sanitary Act, empowering the sanitary authority to give remuneration for extra duties. The order of the magistrates would go before the guardians, who, as a matter of course, would refer the matter to the Local Government Board for their opinion.

Mr. Shee said that the way to test the question would be to have the doctor refuse to give evidence in the case.

Dr. Scully objected to this course, as he would be reported to the board of guardians by the executive officer, and in that way his refusal would come before the Local Government Board, who, not knowing the circumstances under which he acted, might censure him for so doing.

Mr. Casey, C.P.S., thought that what the bench had power to do would be to give an order for costs against the defendant.

Mr. O'Donohoe stated that this course would not test the matter as he required.

After a lengthened discussion, the magistrates refused to give the required order, although they considered that the doctor ought to be paid if he were entitled to it, but

The Magistrates stated that they would bring the subjec under the notice of the board on Thursday next, with a view of having the opinion of the Local Government Board taken on it.

Dr. Scully expressed himself satisfied with this arrangement, and thanked the magistrates for their courtesy.

The case then proceeded.

CERTIFYING OF LUNATICS.

AN APPLICATION FOR A MEDICAL FEE.

DR. NIXON sent to the board the following magisterial certificate, which he received from two magistrates, asking for a fee on the head of same :

We, the undersigned county magistrates, certify that Henry King Nixon, physician surgeon, has given evidence before us, touching the insanity of William Rollins, of Clooncoo, in the county of Sligo.—Signed.

Dr. Nixon came before the board, and said that the dispensary doctor (whose duty it was to examine the lunatic) was unwell, and he (Dr. Nixon) was doing his duty *pro tem.*; and, by a late Act of Parliament, the guardians had the power to pay the examining doctor a fee, when he was not the dispensary doctor.

Chairman—We will have to get up a ratepayers' protection association if these things go on.

Mr. Walker considered as it was a portion of the dispensary medical officer's duty, the substitute of that officer should do it without the guardians being called on to pay it.

Mr. Sidley—The doctor better get the Act of Parliament for the guardians.

Dr. Nixon then withdrew.

Subsequently Dr. Nixon sent in a copy of the Act of Parliament, which runs as follows :—

Notwithstanding anything in section 10 of the Act of the session of Parliament held in the 30th and 31st years of the reign of her present Majesty, chapter 118, to the contrary, it shall be lawful for any two justices causing any person to be examined by any medical officer as therein mentioned, if they think fit so to do, to make an order under their hands and seals upon the guardians of the union to which such person belongs for the reasonable remuneration to such medical officer, and for the payment of all other reasonable expenses in or about the examination of such person, not exceeding in the whole the sum of £2. All moneys so ordered to be paid by the guardians of such union shall respectfully be advanced, paid, and raised in like manner as any other moneys required for supporting and maintaining the destitute poor of such union.

Chairman—But in this case the magistrates merely certify that Dr. Nixon examined the patient, but they make no order on us to pay him anything.

Mr. Sidley—They should state what sum they consider the doctor is entitled to—whether half a guinea or £2.

Mr. Walker—But does this insane man belong to this union at all?

Chairman—Is there such a place as Clooncoo in this union?

Relieving Officer Mahon believed it was in the union of Boyle.

Chairman—Then it is the guardians of the union to which he belongs who are to pay the money.

The Chairman drew up the following minute, which the board adopted:—

The Board of Guardians having considered Doctor Nixon's application for remuneration for having examined a lunatic named Rollins, together with the Lunatic Asylums (Ireland) Act, 38 and 39 Vic. cap. 67, are of opinion that they have no power to comply with the request; because the Act of Parliament requires two justices "if they think fit so to do, to make an order under their hands and seals upon the guardians of the union to which such person belongs for the reasonable remuneration to such medical officer;" and, by the certificate handed in by Dr. Nixon, no such order has been made; and secondly, the union to which the lunatic belongs is chargeable, and there is no townland named Clooncoo in this union.

RESPONSIBILITY FOR THE ENFORCEMENT OF THE ADULTERATION ACT IN IRELAND.

At the Nenagh Board of Guardians a letter was read from the Local Goverment Board referring of a circular of 3rd November last, drawing attention of the Sanitary Authority to those provisions of the Sale of Food and Drugs Act, 1875, 38 and 39 Vic. cap. 63, which prescribe the mode of proceeding to obtain an analysis upon which (if it shall appear that an offence has been committed against any of the provisions of the Act) proceedings may be taken. "The Local Government Board" it says, "desire to acquaint you for the information of the Sanitary Authority, that they have been informed that since the date of the circular an opinion has been given by the Law Adviser of his Grace the Lord Lieutensnt to the effect that under the Sale of Food and Drugs Act, the Grand Jury of the County shall appoint the analyst, as the local authority charged with the execution of the act, and it would appear therefore that the Sanitary authority and its officers are not responsible in regard to the provisions of the Act. In Boroughs in which the appointment of the analyst is required to be made by the Town Council, the local authority would appear to be the Town Council."

Mr. Head, remarked that the Grand Jury was but an evanescent body which only existed for a couple of days at each assizes; and if not in existence how could they conduct a prosecution.

Mr. Kilkelly asked if the analyst had been appointed yet.

The Chairman said he had been appointed by the Grand Jury.

Mr. Head—In that case the solicitor of the Grand Jury would be the person to take up the prosecution.

Mr. Head remarked that there were two grand juries in the county North Riding and South Riding; he wished to know which would be *the* Grand Jury within the meaning of the letter.

After some discussion, the following memorandum was directed to be submitted to the Local Government Board:—

The sanitary authority would like to be informed how the "grand jury of the county," as the local authority, is to be put into motion when cases arise for prosecution when the grand jury is not sitting, and what consitutes the grand jury of the county of Tipperary, separated as it is into two Ridings, each having a separate grand jury.

LIABILITY OF LANDLORDS FOR SANITARY RATES.

At a recent meeting of the Carlow Board of Guardians, the following letter was read from the Local Government Board:—

"Sir—The Local Government Board for Ireland acknowledge the receipt of the minutes of proceedings of the Board of Guardians of Carlow Union of the 3rd inst., containing a resolution in which the guardians request to be informed whether general and special rates made for sanitary purposes, and also burial rates, can be deducted from the rents in the same proportion as poor rates; and in reply, the Local Government Board have to state that general and special rates, made by a rural sanitary authority, for sanitary purposes, would be subject to all the incidents of the poor rates, and should be borne accordingly by landlords and tenants, in the same proportions as rates made for the relief of the poor. As regards the rates levied under the provisions of the Burial Grounds Act, the Local Government Board desire to observe that conflicting legal opinions have been given by very eminent counsel as to the right of the tenant to make a deduction from his rent on account of Burial Rate, and the Board are not aware that the point has ever been settled by a judicial decision.

"The Local Government Board believe that the generally prevailing practice is to make precisely the same deduction as in the case of the ordinary poor-rate, and this practice the Board believe to be most in conformity with the object and intention of the Legislature."

THE REGULATION AND INSPECTION OF COMMON LODGING-HOUSES.

The following circular has been issued to Boards of Guardians by the Local Government Board:—

"Local Government Board, Dublin,
"9th February, 1876.

"Sir,—Adverting to the circular letter of the 6th September last, on the subject of the adoption of bye-laws by sanitary authorities for the regulation of Common Lodging Houses, under the provisions of the Common Lodging Houses Act, the Local Government Board for Ireland desire to acquaint you that having received a communication frsm a rural sanitary authority, by which the bye-laws which accompanied that letter had been adopted, suggesting that the services of the Royal Irish Constabulary should be made available in carrying out their provisions, the Board brought the subject under the consideration of his Grace the Lord-Lieutenant, and the matter having been referred to the Inspector-General of Royal Irish Constabulary, it appears to be considered by him that for the police to carry out these bye-laws would occupy too much of their time. But there is no objection to their enforcing the rule which provides that no keeper of a common lodging house shall accommodate a greater number of lodgers or other persons than that mentioned in the entry of the said house in the register of common lodging-houses. It is, doubtful, however, whether the Constabulary have power to enter common lodging houses at all times, and therefore if the sanitary authority desire to avail themselves of the services of the Constabulary in this respect to the extent above stated, which the Board would recommend them to do, they should make a new bye-law under the fourth section of the Common Lodging Houses (Ireland) Act, 1860, providing for the employment of the Constabulary as officers to make entry and inspection at all hours, and providing a penalty in case of refusal or obstruction. A draft of such a bye-law is annexed.

"Should the proposed bye-laws be adopted the sub-inspector or constable in charge should be informed of the authorised number of lodgers for each house.

"By order of the Board,
"B. Banks, Secretary."

(COPY OF BYE-LAWS)

"Common Lodging Houses Acts, 14 and 15 Vic., cap. 28. 16 and 17 Vic., cap. 41 ; 23 Vic., cap. 36.

"Whereas the —— sanitary authority have, in pursuance of the authority vested in them in that behalf, made bye-laws respecting common lodging-houses in their district, for the well-ordering of lodging-houses, and the separation of sexes therein, and for fixing the number and sex of the lodgers who may be received in each such house, and for promoting cleanliness and ventilation therein, and such bye-laws have been duly approved of in accordance with the provisions of the above-mentioned Acts ; and it is expedient to provide by a bye-law to be made in pursuance of the powers aforesaid, for inspection of such houses.

Now, therefore, we hereby make the following by-elaw, in addition to the bye-laws so made, and approved as aforesaid—

"'The keeper of every common lodging-house shall give access to the same at all times when required by the sanitary officer or by any sub-sanitary officer of the district, or by any member of the Royal Irish Constabulary, who shall be authorised by the sanitary authority to enter such common lodging-house for any of the purposes of the said Act, and any person who shall refuse so to admit such sanitary officer, sub-sanitary officer, or member of the Royal Irish Constabulary, or shall offer any obstruction to his or their entrance, shall be liable to the penalties provided by the said Acts for offences against bye-laws made under the provisions thereof.'"

The Clerk said it was desirable the Constabulary should have authority to enter lodging-houses. It was at night the lodging-houses required to be visited, and the sub-sanitary officer might not be on the spot.

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING FEB. 12, 1876.

Total registered deaths in Dublin and suburbs *	...	225
Ten years average of same week	...	198
Excess of mortality above average	...	27
Ratio of deaths, suburb of Rathmines ...	30	per 1,000
" " " Donnybrook†	29	"
" " " Blackrock ...	22	"
" " " Kingstown ...	11	"
" " Entire Dublin district ...	37	"
COMPARATIVE RATIOS—London	24	"
" " Glasgow... ...	28	"
" " Edinburgh ...	22	"

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases amounted to 32, including 1 from typhoid fever, 13 from whooping-cough, 7 from measles, 3 from scarlet fever, 2 from diarrhœa, &c.

Seventeen children died from convulsions.

Fifty-three deaths resulted from bronchitis, 3 from pneumonia, 1 from asthma, and 6 from lung disease unspecified.

Three deaths were ascribed to apoplexy, 4 to paralysis, 1 each to cephalitis and insanity.

Heart disease proved fatal in 8 instances, liver disease in 1, and kidney disease in 2.

Twenty-four persons died from phthisis, 6 from mesenteric disease, 5 from hydrocephalus, 3 from scrofula, and 1 from cancer.

Ten deaths were caused by accidents, and 1 was homicidal.

Three deaths from diarrhœa, 1 each from scarlet fever and diphtheria, and 2 each from fever and whooping-cough were registered in Belfast.

Five deaths from measles, 3 from whooping-cough, and 1 from fever, were registered in Cork.

Five deaths from whooping-cough and 2 from diarrhœa were registered in Limerick.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF JANUARY, 1876.

JAN. 6th.—O'Leary, Thos. Philip, 37 Wexford Street, Dublin, Lic. R. Coll. Surg. Irel. 1875.

6th.—FitzSimon, Cuthbert Collingwood, 41 Lower Mount Street, Dublin, Lic. R. Coll. Surg. Irel. 1874, M.D. Qu. Univ. Irel. 1875.

7th.—Bleakley, Alex. Slorach, Ballycannon Rectory, Tullamore, King's County, M.B. 1875, and M.Ch. 1875, Univ. Dub.

10th.—Taaffe, Michael, Fountain, Ennis, co. Clare, Lic. R. Coll. Surg. Irel. 1874, Lic. Apoth. Hall, Dub. 1876.

14th.—Longford, Henry, 30 Waltham Terrace, Blackrock, co. Dublin, Lic. R. Coll. Surg. Irel. 1873, Lic. 1874, and Lic. Mid. 1874, K. Q. Coll. Phys. Irel.

17th.—McCarthy, Geoffrey, Kenmare, co. Kerry, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

19th.—Sheppard, Wm. David, 83 Harold's Cross, co. Dublin, Lic. Apoth. Hall, Dub. 1875.

19th.—Boyd, Thomas, Castletown Manor, Ballina, co. Mayo, Lic. 1874, and Lic. Mid. 1874, R. Coll. Surg. Irel., Lic. K. Q. Coll. Phys. Irel. 1875.

20th.—Halpin, Nicholas John, 30 Great Charles Street, Dublin, M.B. 1875, and M.Ch. 1875, Univ. Dub.

20th.—Smith, Richard Baker, Crumlin, co. Dublin, Lic. R. Coll. Surg. Irel. 1875.

20th.—Power, John Joseph, Kilteely, co. Limerick, M.B. 1875, and M.Ch. 1875, Univ. Dub.

21st.—Meredith, Edward Bishopp, 3 Kenilworth Terrace, Rathgar, co. Dublin, Lic. R. Coll. Surg. Irel. 1875, Lic. 1875, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

21st.—Goodman, Francis George, Skibbereen, co. Cork, M.B. 1875, and M.Ch. 1875, Univ. Dub.

22nd.—Smith, George, 15 Clarinda Park West, Kingstown, co. Dublin, Lic. 1875, and Lic. Mid. 1875, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1875.

24th.—Hughes, George Arthur, 1 York Terrace, Cork, M.B. 1875, and M.Ch. 1875, Univ. Dub.

25th.—Davis, William, Spring Lodge, Salt Hill, Galway, M.D. 1874, and M.Ch. 1875, Qu. Univ. Irel.

25th.—O'Sullivan, John Joseph, Medical Hall, New Street, Killarney, co. Kerry, Lic. Apoth. Hall, Dub. 1873.

25th.—Abraham, Andrew Arthur, 124 Rathgar Road, co. Dublin, Lic. R. Coll. Surg. Irel. 1875.

26th.—Armstrong, James Bailie, Castletown, Berehaven, co. Cork, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

27th.—Williamson, John Francis, Ardess, Kesh, co. Fermanagh, M.B. 1876, and Lic. Surg. 1876, Univ. Dub.

27th.—O'Farrell, Denis Paul, Loughrea, co. Galway, Lic. R. Coll. Surg. Irel. 1874, Lic. K. Q. Coll. Phys. Irel. 1874.

27th.—Henderson, Wm. George Hume, Shawburn, Hamilton, N.B., Lic. R. Coll. Surg. Irel. 1875, Lic. 1875, and Lic. Mid. 1875, K. Q. Coll. Phys. Irel.

29th.—Bryson, Wm. Bruce, 24 Charleston Road, Rathmines, co. Dublin, Lic. R. Coll. Surg. Irel. 1873, Lic. R. Coll. Phys. Edin. 1874.

29th.—Ross, David Robert, 20 Ormond Road, Rathmines, co. Dublin, M.D. 1875, and M.Ch. 1875, Qu. Univ. Irel.

REPORT OF THE INSPECTORS ON THE LUNATIC ASYLUMS IN IRELAND.

(*Continued.*)

Poorhouses.—On a general analysis of the mentally affected in this country, as already given in a preceding section of this report, it appears that out of an aggregate between the registered and unregistered, 3,140 were located in poorhouses on the 31st December, 1874, being eleven more than at the corresponding date of the previous year. In the returns obtained by us, through the kindness of the

Local Government Board, we have had these inmates classified under the denominations of idiots, epileptics, and lunatics, as constituting for the purpose of reference the most practical arrangement. The gross total of simple and epileptic idiots or imbeciles amounted to 1,740—758 males, and 932 females, while that of the lunatics, for the most part aged and demented, nearly one half subject to epilepsy, was 1,401—512 of the former and 889 of the latter named sex.

As the inspection of all institutions, whether public or private, containing insane persons, is imposed on us by 5 and 6 Vic., cap. 33, the visitation to union workhouses harbouring as they do about one-fourth of all the registered under treatment, forms no inconsiderable portion of our official duties. The question of how and where individuals labouring under mental affliction, who from their antecedents or the nature of their malady offer no reasonable hope of recovery, can be most appropriately located is one worthy of mature consideration, both in a social and pecuniary point of view. So long as actual benefits are derivable from an extra expenniture on regular asylum buildings, and the particular accommodation afforded by them, it would be unjust to deny their advantage to the insane; on the other hand, however, the public in its ratepaying position has a right to foster economy by an avoidance of uncalled for taxation.

How far then the double object can be most satisfactorily obtained is a problem of interest and importance, whether it be by the establishment of provincial chronic hospitals for the insane at present in, or from year to year likely to become resident in union workhouses, or by setting apart when expedient a whole or portion of a workhouse in each district or county contained within it for the detention of epileptics, idiots, imbeciles, and the like.

Under existing circumstances the tendency of some Boards of Guardians is to disembarrass their respective unions of persons who come within the term insane, no matter how trivial their affection may be, but particularly if they give any trouble. They probably think as the lunatic district at large, which comprises at least one county has to meet, through Grand Jury presentments, the cost incidental to an asylum residence, that not only a special saving to their unions is effected by an enlarged area of taxation, but by their taking advantage of the 4s. weekly rate in aid, for each lunatic when so transferred, a sum of £10 8s. annually, nearly equal to the whole cost of the like inmate of a poorhouse, would be further economised; but this fact should not be overlooked, that not only the difference between maintenance in a workhouse and a district institution, about £14 per head, would have to be paid, but that to obviate the inconvenience and risk from overcrowding, the costly outlay on structural additions to meet continued requirements would eventually be entailed on local charges. The guardians of union B. for example, labour under a fallacy in the supposition that by getting rid of their insane, idiots, epileptics, and the like, they obtain fiscal advantages—forgetful that unions C. D. E. and F. can adopt a similar practice in self protection.

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER VII. (*continued from p.* 131.)

Now for another qualification. When we either actually see or only think of a brick we have a state of consciousness of a thing particularly coloured and extended. There is then we suppose activity of certain elements of the substrata of consciousness which lie in the right posterior and left anterior lobe. But we seem to have two mental states together or in reversible succession; we seem as if we had not only an idea of the rose, but *we* seem to know that *we* have it. We seem to remember the rose as if we had a general consciousness in addition to and yet distinct from another more special consciousness, a sort of "faculty" of remembering the rose. Similarly for other so-called faculties, especially the Will. Let us state an hypothesis explanatory of this feeling. It is that the substrata of consciousness are double, as we might infer from the physical duality and separateness of the highest nervous centres. The more correct expression is that there are two extremes. At the one extreme the substrata serve in Subject-consciousness, at the other extreme in Object-consciousness. (*a*) But it is convenient to use the word double. We have already spoken of the substrata of Object-consciousness. But we shall now consider the relations of the two. We speak first of the substrata of Subject-consciousness.

Subject-consciousness is first in all mentation. This half of the double substrata is made up of nervous arrangements representing the parts of the whole organism *in relation to one another*. Here their representation is in the order from the most general (systemic or organic) movements and most general (organic or systemic) sensations up to the most special movements and most special sensations. By this half of the substrata impressions from the environment are received; it is the passive half; the chiefly sensory half. We say chiefly, for there must be a motor element too, or there could be no notion of the locality of an impression. Sensory action is first and most; the sequent movement represented in these substrata simply serves in the physical process during which the part of the surface of the body acted upon is registered in sub-consciousness; it does not give a notion of externality or of the thing acting. In any impression received, affection of what is called the systemic sensations will be first; there is first, that is to say, a most general sensation (*a*) representing the organism as a whole as being affected before there can be the sensation that it is being particularly affected here or there; this process is usually unconscious or sub-conscious, unless the local impression be excessive. When it is excessive (when there is the psychological state of pain) the impression in many parts of the body, if not in every part, *does disturb the whole system*, causes pallor, faintness, and sickness, developes systemic sensori-motor processes. This is very important, for the implication is that in the slightest local impressions the whole organism becomes affected in the sense that the highest nervous arrangements *representing the organism as a whole* are disturbed. (*b*)

(a) Subject-consciousness is not commonly spoken of as consciousness; it is a sub-consciousness bordering on unconsciousness.

(*a*) The term "sensation" is very awkward here; it is meant that there is a contribution to a state of sub-consciousness, bordering on consciousness. Lewes' doctrine that Sensibility attends activity of all nervous centres would save us from the awkwardness of using expressions which are strictly equivalent to the contradiction of "unconscious sensations."

(*b*) "Ludwig has found that irritation of a sensory nerve has a double effect—(1) it causes the vessels of the part to which it is distributed to dilate; (2) it causes the vessels in other parts of the body to contract, so that the general blood-pressure is raised."—Lauder Brunton, St. Barth. Hosp. Rep., 1875. This

The activity of the substrata of subject-consciousness in health is not attended by what is commonly called full consciousness. They form the anatomical side of what is a continued under-consciousness (persistence of consciousness) and are those most concerned in the wide bodily states which are the physical side of emotions. (*a*) These substrata are in constant slight action and in but slightly varying action. They rise in activity before that of those nervous arrangements which constitute the second half of the double begins.

The second half of the substrata of consciousness represents the physical side of object consciousness—consciousness commonly so-called. These nervous arrangements represent parts of the body in the order from the most special and voluntary movements and sensations to the most automatic and general movements and sensations. So that these like the last represent the whole organism, but in the reverse order; they represent the body in the order of its power of reacting on the environment, not in its possibilities of being acted on. This is the chiefly movement half. Movement here comes first. (*b*) The sense of resistance is first and ever present in this half as the systemic sensations are in the other half. There is first in the former, that is to say, the sensation of the organism as being impeded here or there, as in the latter, of the organism as being affected thus or thus. They are the arrangements by which some part of the organism (already represented as a whole by the substrata of subject consciousness) is re-acting on its environment; the reaction varying much from moment to moment. In conscious states it is not simply that an impression received from the environment developes this reaction; the impression received affects the whole organism, and it is this which leads to the reaction. These substrata serve in what is called Perception as distinguished from Sensation. To perceive a thing is *to refer it to the environment* or to some part of the body. (*c*)

This division into substrata of object and substrata of subject consciousness appears to me to correspond anatomico-physiologically with the psychological distinctions betwixt subject and object made by Spencer and with that by Bain betwixt (*a*) Object and Subject-consciousness.

If the substrata of consciousness be double their duality is but an illustration on the highest level of the duality of nervous arrangements in general. The unit of action of the nervous system is double the unit of constitution; it is "a molecule of two atoms." The lower centres are double, and so are the centres of centres—those which sum up and potentially contain all lower centres. But the noteworthy thing is that in the highest parts of the nervous system the two halves of the double unit are not *mere* duplicates as they are in the lower centres. One half acts before the other, and acts differently

We have already suggested that certain regions of the cerebrum are concerned in object consciousness, which we then spoke of as "Consciousness" only—the right posterior and the left anterior lobe. We have next to speak of the seat of the substrata of the corresponding Subject-consciousness. We believe they are the right anterior lobe and left posterior lobe. By these nervous arrangements we learn how and where our organism is affected, as by the corresponding object consciousness we learn what and where the thing in the environment is which affects us.

What has just been said is but repeating in a more general way what I have said in the paper on the "Nature of the Duality of the Brain," January, &c., 1874. For to speak is to be conscious in words; to perceive is to be conscious in objects. But such full consciousness arises out of, and is posterior to, the corresponding under-consciousness called subject consciousness. For example, the automatic and unconscious (or sub-conscious) reproduction of words and images of things precedes, I there argued, that reproduction of them which is attended by full consciousness.

The above view is not parallel to the view popularly taken that we have a consciousness apart from, and as it were served by quasi-independent faculties of "volition," "memory," &c., and also sometimes governed by them. On the contrary, these so-called faculties are only different sides of constantly varying states of object consciousness which *arise out of prior states of sub-consciousness or unconsciousness*, directly out of sub-consciousness. It is supposed that there is a constant play betwixt the two—an unceasing rhythm. Spencer writes:—"It seems to me that the consciousness of self and the consciousness of not-self are the elements of an unceasing rhythm in consciousness—a perpetual alternation ordinarily so rapid as to escape observation, though occasionally so much retarded as to be observable. Like the divergence already set forth (§ 353) from Sir W. Hamilton's interpretation of the antagonism between Sensation and Perception is the divergence that arises here; this second divergence being in truth a corollary from the first. Just as before we saw that Sensation and Perception respectively dominate in consciousness with degrees of strength that vary inversely, thus excluding one another with varying degrees of stringency; so here we shall see that the consciousness of self and the consciousness of not-self are ever tending each to exclude the other but each failing to do this for more than an instant, save in those exceptional cases where it is raised to extreme vividness."—Spencer's "Psych.," vol. ii., p. 438.

This doctrine is supported, I think, by facts which we shall adduce later when speaking of the After Effects of

---

shows that a local irritation, when excessive, affects the whole organism. It is believed, however, by physiologists, that the irritation is conveyed only so far as the vaso-motor centre—that is only as far as the medulla oblongata.

(*a*) *Emotion* is the most general feeling; we are always in some state of feeling, just as much as we are always alive. What are commonly called emotions, meaning particular emotions are variations of this constant state. The physical process underlying emotion involves the whole organism, and each particular emotion is, so to speak, a special attitude of it. When this or that particular emotion predominates these or those parts of the body have the leading excitement or depression. *Sensation* is a less general feeling; its physical process involves much of the organism, but some part of it especially. Perception is least general, most special, and the physical process in it involves some part of the body, and is mainly the reacting of some part definitely *after* a local impression which has but faint if any attendant sensation. So there are gradations of feeling from those forming part of subject-consciousness only to those rising into object-consciousness; there is in this ascending series of mental states diminishing consciousness of the organism and increasing consciousness of the environment.

(*b*) It is not meant that movement begins here without prior excitation from some afferent nerve or nerve centre corresponding to afferent nerves.

(*c*) Obviously, even by this definition Sensation and Perception are not abruptly separated. A local pain *as a pain* is an affection of subject consciousness. A sudden and severe pain anywhere, or in many places, at any rate (*i.e.*, the nervous change underlying the pain), affects the whole organism; it evidently leads to changes in the circulation of the whole body. To know that the pain is in this or in that part of the body is an affair of object consciousness, and implies local movement, actual or nascent of some part of the body. At least the principle is the same; although we cannot say that the part of the body in pain is part of the environment. It is a part which for the time is considered as separate from the rest of the organism by a high degree of local independence of feeling. Moreover, the particular emotions, those which vary from the common feeling, are known as emotions by being referred to the environment; we attribute modesty to the daisy, just as we attribute redness to a brick.

(*a*) Bain gives several distinctions ("Emotions and Will," 3rd ed., p. 575, *et seq.*). I do not follow Bain's order in the subjoined. (1) "The feeling of expended muscular energy as against sensations wholly passive." This nearly agrees with the distinction into *chiefly* motor and *chiefly* sensory elements of the two substrata. (2) "The contrast between Indifferent Feeling and Pleasure or pain fuses itself with the Object and Subject contrast." Thus it seems to me to accord with the two orders in which I suppose the sensation to be represented in the substrata. (3) "The contrast of Intellect and Feeling coincides to a very large extent with the contrast of Object and Subject." (4) "Definite Feelings connected with Definite Movements; Feelings independent of our Movements (Subject)." This nearly coincides. (5) "Experience common to all (object), as against experience special to each (subject)." This last is a very important distinction, and again, there is a harmony.

Excessive Nervous Discharges. We shall see that Exhaustion produced by these discharges and also in other ways of a higher centre allows the one next lower, the one next least automatic to *spring into activity*. The substrata of object consciousness are the higher of the two substrata. With exhaustion of the substrata of object consciousness there goes increased activity, or let us say excitement, of the substrata of subject consciousness. The exhaustion may be only very slight, as in the "brilliancy" of the mentally over-fatigued, which brilliancy is owing to an excitement of the substrata of subject consciousness *permitted by* slight and partial exhaustion of the substrata of object consciousness—there is metaphorically speaking loss of control. The "rhythm," unceasing in health, is stopped by disease, or goes on at a lower level, because the use of one half, always first the object half, is temporarily lost, or is impaired. Let us take a very simple illustration. In a delirious hospital patient there is a loss or defect of object consciousness from exhaustion of their substrata. The facts proving this assertion are that the patient does not know where he is ; does not know any persons or objects rightly. But there is increase of his Subject-consciousness, for he believes that the ward is the place most familiar to him—the place where he works, or his home, and he takes the nurse for his wife, and a boy patient for his nephew. He is, in short, to borrow both ideas and words from Bain, defective with regard to "experiences common to all (object)" and exalted "with regard to experiences special to each (subject)."

Although we speak of the correspondence betwixt the organism and the environment, what occurs anatomically and physiologically is a rhythm betwixt the two sides of the brain (or betwixt two differing units of one side); one representing the organism as it is acted on in this or that part, the other as reacting on this or that thing in the environment. This is evidently all that can occur when we are thinking about the action of absent persons in places at a distance. To perceive a brick is to refer it to the environment ; we so refer it just as certainly when we think of the brick as when we see it. But it is equally certain that when we have the fullest object consciousness when ws see a brick before us, that what we are concerned with (anatomists and physiologists) is a state of our own organisation—specially a state of our own nervous system produced in some unknown way by the brick acting on us and by our reacting on it. As repeatedly insisted on, the only difference betwixt seeing the brick and thinking of it is a difference of degree. To perceive a thing is, we repeat, to refer it to the environment ; we do this just as certainly when we think of the brick as when we see it. The former is commonly called an idea, the latter a perception. But an idea is only a faint external perception, and an external perception is only a vivid idea. In the former the externality also is faint, in the latter strong. For in the former the environment itself is faint, in the latter vivid. In no case can we think of a thing except as in the environment ; our idea of justice is an attributing a certain feeling we have to some person or persons. In thinking of an object there is of course the difference that the environment is, to speak shortly, "remembered," or constructed. This difference of mere degree sinks into insignificance before that difference implied by the rhythm of subject and object consciousness, and illustrated by the unconscious and automatic reproduction of images of objects *before* that perception which is a conscious and voluntary reproduction of them.

Just as localisation of ideas, or rather of the substrata of ideas means anatomically localisation of certain highly complex and special nervous arrangements representing particular impressions and movements, so localisation of symptoms in epilepsies means the same. A convulsion from disease of the brain is a *brutal* development of the function of the substrata of some ideas. We have to bear in mind that the discharging lesions in epilepsy are not only local, but that their discharges being very strong, lead to excessive developments of the functions of that part of the brain which they happen to involve ; the discharges of health lead to sensori-motor actions ; the discharges of epilepsy not only develope the functions of a part brutally, but develope nearly solely the functions of that one part ; there may occur motor symptoms almost only and sensory symptoms almost only.

Thus convulsion of the hands may represent a violently active state of the motor elements only in the substrata of tactual ideas ; convulsion of the tongue, palate, lips, &c., of the substrata of words. In some cases of migraine we have the corresponding sensory elements. Let me take a parallel case from physiological experiment. It is well known that irritation of definite areas of the skin of a headless frog provokes an excitation of the nerve cells in some part of the cord by which certain related movements are developed. This, however, is not the illustration. To give a case analogous to that of convulsion in man we must suppose the frog to be strychnised ; then the cells in the animal's cord are raised to a degree of instability analogous to that of the cells of the cortex in a discharging lesion in the epilepsy of man. They discharge strongly, rapidly, and many of them at once. From this results a convulsion (in the frog, tetanus) that is a sudden, rapid, and brutal development of numerous movements.

In the brutal discharges of epilepsies we have no mental states except the crudest, as of clouds of colour, numbness of the hands, &c. Let us speak of epileptic discharges beginning in the substrata of consciousness, and also try to show that the epileptic paroxysms dependent on discharges of these substrata differ according to the part of the substrata excited. We speak of the genuine epilepsy of authorities.

The paroxysm may begin by loss of consciousness, the patient having not the least precursory sensation. When this is so, we have no help from him towards localising the discharging lesion in any part of the substrata of consciousness. But sometimes the loss of consciousness is preceded by some crude sensation. It is very often a feeling referred to the epigastrium, and this is, I think, a coarse development of certain systemic sensations, that is, of sensations leading in Subject consciousness, or it may be coloured vision, that is, a sensation leading in Object consciousness. Now we speak of movements: these we can see ourselves, or infer them by their effects. A paroxysm sometimes begins by pallor of face, that is, by coarse development of movements leading in Subject-consciousness. There are the movements corresponding to systemic sensations. Then there is often a brutal development of movements of the eyes (spasm of the ocular muscles), that is a development of movements leading in object consciousness. These are the motor correlative symptoms of coloured vision.

Different modes of beginning of epileptiform paroxysms necessarily point to differently seated discharging lesions. That we may be quite unable to declare exactly where the discharging lesion is in any of the instances just alluded to does not invalidate this very general remark. We may at any rate say that the paroxysms spoken of begin by discharges in the very highest nervous arrangements, for loss of consciousness occurs almost instantly after the warnings spoken of. But we spoke of "several highest." There are the highest centres concerned during Subject consciousness (left posterior lobe being sensory, and right anterior lobe motor), and there are the highest centres concerned during Object consciousness (right posterior lobe sensory, left anterior lobe leading motor).

We begin with sensations. The left posterior lobe is the lobe where the substrata represent sensations in the order from the most general (systemic) to the most special (sight) ; the right posterior lobe where sensations are represented in the reverse order. They correspond respectively to the order of representation of sensory elements in Subject and Object consciousness. Hence a fit beginning by coloured vision I think most often depends on a discharge beginning in the right posterior lobe, whereas discharge beginning in the left posterior lobe should most often produce first such brutal development of sensation as that feeling referred to the

epigastrium by many epileptics. I suppose this is a brutal development of certain systemic sensations. It accords with this opinion that there is often a deep emotional state, "a fear," "sensation of horror," &c., attending the epigastric feeling.

I do not pretend to know that there are these particular local differences in representation. I am only certain that there are the several kinds of fits, and thus that the discharges must be differently seated. I certainly do not pretend to know that there is such an abrupt separation of duties betwixt the two posterior lobes as the above illustrations imply. For several reasons I believe there is less difference betwixt their sensory functions than there is betwixt the motor functions of the twin anterior lobes. Again, the discharging lesions may be in any one of numerous parts of either of the posterior lobes, so that different sensations may be developed; some epileptic seizures begin by an "aura" of noise. I nevertheless consider that some hypothesis is necessary in guiding investigation in these most difficult cases of epilepsy, and I submit the above on

We now speak of the *first* effects of epileptic discharge of the anterior lobes. They are chiefly turning of the eyes and head; if the head and eyes turn to the left there will be discharge of the right cerebral hemisphere, if to the right, of the left cerebral hemisphere. Vertigo in epileptics is on its physical side a motor symptom; even when unattended by outward movements it implies nascent movement of certain parts of the body, and this depends on slighter epileptic discharge of those parts of the anterior lobe than those discharges which make them actually move.(*a*)

There are often organic motor symptoms, as contraction of the arteries, especially of the face. We should theoretically expect that there would be also slowing or stopping of the heart from excitation of nervous arrangements representing the quasi-motor fibres which inhibit the heart. There *is* stoppoge of the pulse at the onset of some paroxysms of epilepsy.(*b*)

I should imagine that nerves for the arteries (systemic and pulmonary) would be more represented in the right side of the brain, and the inhibitory fibres of the heart more on the left side. In the lower animals the right pneumogastric has, according to Arloing and Tripier, more to do with the heart, the left more with respiration. In some animals the reverse obtains, as regards the splanchnics. The section of the right causes comparatively little sinking of arterial pressure. These peripheral differences, one must suppose, imply differences of representation in the highest centres. One would expect *d priori* the inhibition of the heart to be most specially represented in the leading motor side (left anterior lobe or left hemisphere generally). I here add a quotation from Brunton bearing on the representation of the systemic sensori-motor processes concerned in vomiting in centres so high as the corpus striatum and optic thalamus:—

"Budge states that the cerebral centre for the movements of the stomach is the *right* corpus striatum and optic thalamus, especially the latter. Irritation of these parts causes the stomach to move, while irritation of the corresponding parts on the left side of the brain have no action whatever. From this observation we are led to suspect that when any irritation exists in the right cerebral hemisphere it will occasion vomiting more readily than irritation in the left cerebral hemisphere, and according to Budge, this is actually the case" (Lauder Brunton, *Practitioner*, Dec., 1874). Dr. Brunton refers to an experiment by Gee on a dog (Clin. Soc. Transactions, 1860). Gee injected a large dose of apomorphia (two grains) into a dog. The dog vomited, and in two or three minutes began to course round the room in which the experiment was performed in a curiously persistent methodical manner. Brunton (*op. cit.*) says, "This effect of apomorphia points to an action of the drug on the nervous centres, and is all the more interesting when we remember that Budge placed the cerebral centre for the stomach in the *right* thalamus opticus."

(*To be continued.*)

(*a*) From theoretical considerations I think it most likely that discharges of the right anterior lobe should cause nascent or actual movement (turning) of the whole body, and thus the sensation of the body itself moving, and that if the discharge of the left anterior lobe caused vertigo, it would be from nascent or actual movement of the eyes, and thus there would be the sensation of outward things moving.

(*b*) One would not expect the systemic movements to be so specially represented as the higher movements, those of the eyes and hand, and not so separate from their corresponding sensations (systemic sensations). For example, the connection betwixt sensory nerves from the intestines and their corresponding motor nerves would be more closely organised and also more organised in the lower centres. Then, on the contrary, as regards the most special sensations and movements, one would, I think (considering our power of forming new or "ideal" combinations out of our actual experiences), expect them to be represented more widely apart and less certainly connected. But in the most special sense the separation would not be absolute. Thus in some cases of migraine there is not only a development of colour, but a zigzag outline; this, I presume, implies an excitation of motor elements of such elements as in health serve in the "insect" vision of giving us ideas of the roughness, small patterns, &c.

ON TOPICAL BLOOD-LETTING. (*a*)

By E. D. Mapother, M.D.,

Professor of Physiology, Royal College of Surgeons; Surgeon to St. Vincent's Hospital; and late Examiner in Surgery, Queen's University.

When we draw blood by leeching, cupping, or incision to relieve hyperæmia of organs or regions, we do not expect that the abstraction from the amount of the entire circulating fluid will afford the aid which is so often given. Each leech, for instance, removes scarcely 1-500th of the total blood, and a dozen of them applied to an adult cannot be supposed to depress sensibly the general vaso-motor force. For the control of the vaso-motor influence of a special organ or region no therapeutical agent can as yet be selected with confidence.

Topical blood-letting acts in two different ways—namely, (1) by deriving from the arterial circulation of the affected part—that is, letting blood easily escape from other vessels having a common origin—and (2) by emptying the veins which carry back the blood from the part to the heart. The vessels then can resume their normal calibre, and can take up effused materials, which they do with surprising quickness. Professor George Johnson's well-known illustration of the first way is most accurate and intelligable. When his opposite neighbour, Poole, the royal tailor, illuminates for some glad event, the Savile-row main is largely depleted, and gas is derived most inconveniently from Dr. Johnson's house. The gas mains have, however, no regulating power, such as the muscular arteries have, and this derivative mode of bleeding is seldom applicable, inasmuch as few arterial trunks send branches to organs and likewise to superficial spots whence we may bleed. For example, to relieve hyperæmia of the tissues supplied by the ophthalmic branch of the internal carotid artery, can section of a branch of the temporal offset of the external carotid avail much?

Still more useless is bleeding from the capillaries or veins which indirectly communicate with the vessels of the inflamed organ, and absurd is the only term applicable to the French practice of revulsion—for instance, leeching near the knees in cases of congested uterus or ovaries.

The blood returning from an inflamed organ is that most altered by the pathological process. For this reason and to give direct relief to the vessels of the part, we should, if possible, drain from the actual vein, or the veins with which it connects most fully and quickly provided they be within reach.

(*a*) Read before the Surgical Society of Ireland, Friday, February 18, 1876. The discussion will be found at p

I purpose to illustrate some of these anatomical relations, and if many of them are already known to you, bear with any attempt to attach to descriptive details memoranda of practical interest.

The action of topical irritants may be explained in the same way as the action of depleting measures from the part. Unaware that most organs can be drained from their special veins, surgeons of the past generation often felt that the only resource was general blood-letting. For example, let me cite, as regards the organ already alluded to, Mackenzie, who declares "scarification of the conjunctiva is useless, or even hurtful, in iritis. . . . The patient who could not previously discern the face of a person standing before him, except as a mere mass, will often exclaim, on opening the eye after venesection, that he sees clearly." Direct incision of a congested conjunctiva is plainly superior to leeching the temple.

The ophthalmic vein empties into the cavernous sinus, which connects with the two petrosal and lateral sinuses. By leeching, therefore, near the angle of the lower jaw, and over the mastoid emissary vein, we drain very directly from the eye, and there is now in St. Vincent's Hospital a man whose eye was saved from the ravages of iritis by these means. In a case of retinal apoplexy which Dr. Jacob lately saw with me, the best results followed leeching and subsequent blistering over the mastoid. The late Professor Jacob always selected this point for leeching in ophthalmic cases. That it was the usual bleeding point in every form of disease amongst the Egyptians appears from the writings of Alpinus 300 years ago.

The cerebral hemispheres send their blood back by the superior longitudinal sinus, which freely communicates with veins on the septum of the nose, through the foramen cæcum, and, with those of the scalp, through the parietal foramen, about one inch and a half in front of the posterior superior angle of that bone. If delirium pointing to active, or coma to passive hyperæmia suggested blood-letting, it can be done on the nasal septum—a place from which salutary bleeding so often arises. In no part of the mucous tracts are the vessels so near the surface. It may be noted that epistaxis does not occur from domesticated animals, and in their skulls the foramen cæcum (or, as it might be better named, the superior ethmo-frontal opening) does not exist. The circulation in these creatures is not urged on occasions such as arise in man's brain-work, and their horizontal posture renders valves in the veins of the head and neck useful, whereas man does not possess them. Epistaxis can never be regarded as a mere local flow, but as an escape for congestions of more important parts than the nasal septum. If the site of the emissary parietal veins, which is about four inches in front of the occipital protuberance, be made clear for leeches, by cutting the hair and washing the scalp, blood will freely flow.

In sunstroke and in severe concussion it is believed that considerable and sudden arrest of circulation occurs, and blood-letting at the above-named points would be indicated.

Extensive and promiscuous leeching of the scalp can only act in the way of general blood-letting.

If hemiplegic symptoms show that the base of the brain needs depletion, leeching over the mastoids will give any amount from the lateral sinus. Otitis is relieved in the same way, as all the blood of the organ of hearing escapes by the same channel. The spinal veins are so intricate in their communications that depletion of any of them may be easily secured by drawing from the skin over any part of the vertebral column. The ready action of irritants, like blisters or depressants, like cold in the same region, may be similarly explained. The great drain which aspiration to the chest secures might be utilised in head and spinal congestions by augmenting inspirations in the way suggested, for drowned persons, by Silvester, even if the patient were comatose.

The face and neck are more easily drained of blood than any other region, owing to the absence of valves in the veins, and leeches near the angle of the jaw will draw both from the sinuses and from the tonsillitic and palatine veins, all of which freely communicate with the pterygoid plexus. If, however, a congested or œlematous spot along the mouth, pharynx, ar larynx can be reached, the scarificator is to be trusted.

The difficulties and danger of jugular venesection have banished the operation, but all its advantages can be had by leeching over the thyroid body, as the venous plexus there freely joins the superficial and deep vessels, returning from the head to the innominate veins. The rate of venous flow is here some 200 feet per minute, while in remote veins it is not one-tenth as rapid. The small size and compressibility of these vessels insures that canalisation is unlikely, and the flow from the leech-bites can be easily stayed. Leeches over the sternum can scarcely relieve congestion in the larynx or trachea, while they would draw very directly if fixed near the thyroid veins. The veins from the pericardium mainly return to the internal mammary, and would be drained by leeches over the third, fourth and fifth intercostal spaces at the edge of the sternum, especially on the left side. If, as so often occurs, there be pleuritis as well, the leeches will serve a double purpose, for the pleural veins also empty at these spots. Here, also, as the arteries supplying those membranes and the veins returning their blood are so closely contiguous, local blood-letting would act in both the ways I have mentioned—the deriving from neighbouring arteries and the emptying of veins returning from the inflamed part.

The lungs clothed with serous membranes, which isolate them from the chest walls, cannot be depleted by draining the surface of the front, sides, or lower part of the back of this region, but may on the left side, where the superior intercostal receives the bronchial veins near the fifth intercostal space. At about the third intercostal space of the right side the bronchial veins join the azygos, a trunk which has already received the intercostals and left bronchial veins. The bronchial vessels mainly supply the mucous surface, and can be drained by the sources just mentioned. The fittest site for leeching would then be over the third space, between the spine and scapula. Last Monday, in St. Vincent's Hospital, a girl, recovering from acute rheumatism, was seized with sudden and intense dyspnœa, due, it was believed, to pulmonary embolism. Free leeching in the place indicated gave the most surprising relief. Congestion of the pulmonary circulation, such as has been so often seen during the past two months of bronchitic mortality, could be better relieved by leeching over the thyroid plexus. When surgical injuries to the lungs arrest breathing power, the right heart must be distended, and thyroid bleeding seems clearly indicated. The same step seems most advisable in all those frequent medical cases which obstruct the pulmonary circulation, and overload and palsy the right ventricle. Over forty years ago Professor John Reid proved the wonderful preventive power of jugular bleeding, especially from the lower orifice, over death in drowned and hanged animals, and those poisoned by drugs which paralyse muscular tissue. Blood readily passes between the right auricle and ventricle during all conditions of the heart.

The abdominal wall is supplied by the internal mammary, lower intercostal, and epigastric vessels, while the organs within are connected with the aorta, portal, and inferior caval veins. They are, moreover, separated by a great serous cavity. Leeching the skin of the belly may, therefore, drain the inflamed parietal peritoneum, but cannot sensibly affect the circulation in the stomach, intestines, liver, or spleen. These organs return their blood by the portal vein, and draining it at the rectum is the fittest indication when they are congested or inflamed.

If Luschka's statement that the umbilical vein, or ligamentum teres, of the adult is constantly pervious from the left branch of the portal to the deep epigastric be correct, leeching round the navel may be direct and effectual in inflammations of the liver and all other organs

discharging blood by the portal vein. This anatomical point, however, requires confirmation.

For acute dysentery of the tropics and other inflammatory affections of the abdominal organs, a hundred or two of leeches have deen used without avail, according to writers of the last generation, while half as much blood drawn quickly from the arm produced a profound impression on the system.

There is no organ which has so special a blood supply as the kidney. Insulated in a mass of fat, it joins no other part by vessels except on the left side the testis, by the spermatic.

Renal congestion can, therefore, be scarcely influenced by leeching, or cupping the loins, and the good supposed to follow them must be attributed to the warmth, rest, and low diet which usually are enforced, the first determining to the skin to the relief of the renal arteries; the others checking the formation of nitrogenised compounds. The labour of the organ is lessened by all these means.

The testicle returns its blood by the spermatic veins, and as these vessels pass through the groins and join the superficial veins of the region, leeching there is best calculated to relieve the organ. The veins of the scrotum return to the superficial pubic and epigastric, and puncturing them I have found valueless in cases of orchitis, whilst the risks of erysipelas or ecchymosis forbid leeches. Puncturing as deep as the tunica albuginea has been recently urged by Mr. Henry Smith, and it probably does the good by the loss of blood from the congested vessels. If the inflammation is confined to the epididymis, as is usually the case, puncturing the fibrous capsule of the body of the organ could scarcely act by lessening tension.

The anus has been often selected for leeching in hepatic congestions, but as it is only the superior hæmorrhoidal veins which return to the portal vein, any external bleeding can only be indirect. The middle and inferior hæmorrhoidal veins go to the internal iliac. In the male nothing can be more intimate than the anastomosis between the veins of the bladder and prostate and rectum, and hæmorrhage from one of these regions is often vicarious with that of the other. Mr. Fleming will recollect a case which we both saw, in which the cessation of hæmorrhoidal bleeding was followed by hæmaturia, the source of the blood being clearly vesical.

To draw blood in acute cystitis or prostatitis the surface of the rectum is the fit site, and as leeches will scarcely fix there, it is better to puncture one or two veins with a narrow long bistoury, the gut being held open by a speculum.

Concerning obstetric subjects, I always speak with diffidence. While it must be acknowledged that we have learned much from the practice of letting blood by direct incision of the womb for congestive or inflammatory affections, it appears necessary that in the case of virgins we should seek some other source for depletion—the need, on account of moral reasons, is obvious—and anatomically the uterine plexus is slightly developed in the unimpregnated, and depletion from the labiæ or rectum will drain more fully. Around the rectum there is a free junction between the superior hæmorrhoidal and uterine veins.

The veins in the limbs, deep and superficial, join at most numerous points, in order that the circulation shall not be interrupted during muscular action. Leeching the skin over an inflamed joint or periosteum is, therefore the same as opening the vessels coming from the invaded part, and hence the undoubted efficacy of the measure in such cases. By the way, it is remarkable that we so rarely find the muscles the seat of inflammatory action. The rapid flow of blood, urged on by the muscles themselves, which are like hearts to the veins, may account for the immunity, whereas the fibrous tissues, so sparingly supplied, are often inflamed in the subacute way, and topical blood-letting is most efficacious. When treating aneurisms by complete pressure, leeching over the sac should give aid by lessening the tension of the arrested blood, relieving it of serum and increasing the fibrin. In cutaneous inflammations, erysipelas, acne, &c., the flow of blood and its effused fluids by incisions is too obviously efficacious to need comment.

Venesection at the bend of the elbow is almost a thing of the past, and to the question of general blood-letting I do not allude, but in severe whitlows and synovitis of the wrist-joint it gives striking relief as a topical measure.

The same may be true of opening the internal saphena vein in acute inflammation of any part of the lower extremity.

As to the modes of topical bleeding, leeching is very generally applicable; and the German practice of puncturing the left side of the animal, so as to open the last of the gastric pouches—Bdellatomy, as it is termed—is worthy of imitation, as blood flows far more rapidly, and the quantity is trebled from each bite. Cupping over the bites when the leeches have dropped off draws blood quicker than stuping, and the bleeding will more readily stop, for the blood coagulates, its gases being exhausted.

Still, without dread, we cannot order the introduction of leeches into the nasal, pharyngeal, rectal, or vaginal cavities; and puncturing the veinlets and aiding the flow by irrigation with warm water may be well substituted. Incisions draw blood more freely, and the bleeding is more easily stopped. I have often bled from the nasal septum by touching the mucous membrane at three or four points with a sharp long bistoury, the ala nasi being fully everted. The curved abscess lancet, or the pointed uterine scarificator of Mayer, is in some situations more convenient. Collin's modification of Baron Heurteloup's artificial leech is most effectual on the skin, and it might be lengthened to suit for use in mucous passages. The circular shape of the blade secures cross section of the little vessels, and the pump covers six incisions, if necessary.

To give straightness to the discussion which I trust will ensue, let me recapitulate some of the organs and the superficial spots whence they may be directly drained: the eye at the mastoid process and angle of jaw; the cerebral hemispheres at the nasal septum and posterior superior angle of parietes: the base of brain and ear at the mastoid; the right heart over the thyroid body; the pericardium and front of pleuræ outside the edge of sternum; the lungs along the bases of scapulæ, and the digestive viscera from the rectum. From the veins of this gut also, those of the bladder and prostate, uterus and ovaries can be depleted.

A CASE OF IMPACTED EXTRA-CAPSULAR FRACTURE. (a)

By F. W. Warren, L.K.Q.C.P., L.R.C.S., &c.,
Assistant-Surgeon to Steevens' Hospital.

The morbid specimen which I have the honour of laying before the Society is a case of "Impacted Extra-Capsular Fracture" of the neck of the thigh-bone, with perfect osseous union. It possesses some extremely interesting features, which, I think, render it worthy of being brought under the notice of the Society. I took the specimen from the body of a male subject in the dissecting-room of Steevens' Hospital. I therefore regret that I possess no life history of this specimen, or details of the nature of the injury other than the anatomical and pathological appearances observed subsequent to death. The man was apparently about 60 years of age, and greatly emaciated. In the recent state, prior to any dissection being made, the left lower extremity was permanently everted and shortened to the extent of 2½ inches. The area of motion existing in the hip-joint was limited, particularly the motions of extension and adduction. At a certain point flexion of the limb was suddenly arrested; while rotation and abduction were comparatively free. Thus, within the area of limited

(a) Abstract of a communication made to the Dublin Pathological Society, from a shorthand report.

motion the movements of the limb were quite free. On examination, a large bony mass could be distinctly felt projecting posteriorly to the joint; a second irregular sharp mass of bone could be felt in front, below Poupart's ligament. The right lower extremity was fixed in a semi-flexed position at the knee-joint, the right knee being also directed across the opposite limb, as if to compensate for the extreme shortening of the injured side. The upper extremity of the right clavicle was in a state of caries, a large ulcer existing in the soft tissues over the bone. A large abscess was discovered beneath the left clavicle in the sheath of the subclavius muscle. There were chronic ulcers on the legs, and cicatrices corresponding to others which had healed. The heart was fatty, and the liver and kidneys in an advanced state of amyloid degeneration. In fact, there was not a sound organ in his body.

With the kind assistance of my colleague, Dr. Bookey, I made a very careful dissection of the left hip-joint. The glutæi muscles were in a state of atrophy, the glutæus minimus being attenuated almost to a fascia. The external rotators of the joint were perfectly normal and healthy, and even seemed to be somewhat hypertrophied, the pyriformis being extremely well developed. On removing the muscles we found a large bony mass almost obscuring the joint in front and behind, so much so, that we first thought that these osseous projections must be the result of chronic rheumatic arthritis. On cutting the capsular ligament, which was quite healthy, however, this opinion was quickly dispelled, for the cartilaginous head of the bone was perfectly smooth and quite healthy. The acetabulum was also perfectly healthy and free from disease. The lig. teres was intact and normal. The remarkable external features of the specimen are as follows:—Viewed from behind the neck of the bone is completely obscured by this large bony mass, which is the great trochanter, the cartilaginous head of the bone being alone visible. An osseous ridge of new bone is also seen below trochanter, running upwards and outwards along the posterior intertrochanteric line, and terminating above in a conical projection which surmounts the shaft of the femur and is in the direction of its longitudinal axis. The summit of the trochanter major is above the level of the head of the femur, and is separated from this conical projection by a distinct depression. Looking at the specimen from its anterior aspect, the neck is observed at right angles to the shaft. Along anterior intertrochanteric line no osteophytic projections are visible, constrasting strongly with the enormous bony outgrowths which form the cup-like cavity on posterior and inferior aspect. The second bony mass on inferior aspect and in front of the neck springs from lesser trochanter, and passing beneath the neck of the bone, is continuous with the lower part of the trochanter major, forming an osseous cup in which the globular head lies. Viewed from above it presents a similar appearance to a ball in a cup. The trochanter major has been carried backwards and inwards probably by action of glutæi muscles. A large bony mass which surmounts the shaft and the ridge of new bone corresponding to posterior intertrochanteric line seems to be an ossifically united fracture passing through the great trochanter and detaching it from the shaft. What probably occurred was this:—The neck of the bone was broken at its junction with shaft and driven into the cancellated tissue between the trochanters in an oblique direction, the broken extremity of the cervix being forcibly impelled against the trochanter major and detaching it, the lesser trochanter being probably also fractured. The perfect ossific union, the exuberant osteophytic growths, coupled with the extreme density and weight of the bone, evidently point to a fracture occurring at an early period of the patient's life, he being at the time in robust and vigorous health, for it is hardly credible that such perfect consolidation could have taken place under any other conditions.

Here is, I think, a somewhat analogous specimen from the Museum of Steevens' Hospital, in which no union has taken place. On referring to some leading authorities on this subject, I find a somewhat analogous case, at least in appearance, tabulated in the late Professor Smith's book on Fractures, page 93, Case 41, in which similar osteophytic growths were thrown out, nothing like, however, in so marked a degree as in the present specimen. The anterior intertrochanteric line also in his case was the seat of these growths, thus differing from the specimen.

Clinical Records.

CASES OF SKIN-GRAFTING.

By C. P. Coombs, M.D. Lond.

The results of grafting pieces of living skin on wounds are so seldom made public now that the operation seems to be going out of repute. Several cases which have occurred in my practice are subjoined, to represent the measure of success which may be expected. As a rule, the relation of surgeon and patient was such that it was not necessary to explain at length that a piece or pieces of skin were about to be taken from the arm and planted on the sore place; but the sleeve was raised by the patient, while, with sharp scissors and a pair of forceps, I raised and rapidly snipped off enough skin to form four pieces, each about one-eighth of an inch in diameter. A little practice enables one to take the right amount, and to avoid removing any of the fat with the skin. The wound must be in a healthy state, with good granulations; it is supposed to be clean, and placed conveniently, when the skin is snipped from the arm and quickly divided. Each of the fragments is placed in a little hollow, which the tip of the forceps will make in the surface of the wound, as little bleeding as possible being produced. Broad straps of plaster are then passed over the wound, so as to keep the grafts in position, and the limb *must be placed at rest*. Legs must stay in bed. This rule is most important, and I attribute most of my failures to my patients having broken it. Four or five days should elapse before the plaster is removed, and then a simple dressing, such as carbolic lotion, is to be employed. The white, soaked epidermis will probably come away, at or soon after the first dressing, and the success of the graft is uncertain for some days, until the island of skin, at first nearly transparent, appears, in colour bluish-white, raised above the granulating surface. Some of the benefit to the wound arises, no doubt, from the extra care given to it when "a piece of skin has been taken off one place and stuck on another place," which is highly entertaining to the patient and friends. I give *all* the cases I have grafted, and wish to "nothing extenuate," merely reminding the reader that the treatment was not carried out in a hospital, but generally in a poor cottage.

Case 1.—E. W., 37, married woman, had had an indolent ulcer on one leg for ten years. At time of operation it was in size about four inches by three. After grafting the wound completely healed, but the new skin gave way some months later, not to the original extent, however.

Case 2.—C. M., 60, a healthy old shepherd, had been bitten in the calf by his dog, and the resulting wound extended until it was a circle three inches in diameter. He would not stay in bed, and the grafts did not succeed. The treatment with scraped cuticle failed also. The sore healed some months later under other treatment.

Case 3.—J. R., 55, a feeble man for his age. The skin of one leg had all sloughed, from the knee to the ankle, and the resulting sore had healed except one portion, four inches by one and a-half inches. This part having been in an indolent, unhealed condition for a long time, two grafts were applied, and both adhered and were successful, the wound soon closing.

Case 4.—R. H., 76, an old man, had been suffering from carbuncle in the upper part of the back for six weeks. The resulting sore had no disposition to heal, so four grafts about one-sixth of an inch in diameter were applied. On the fourth day, when the wound was dressed, no sign

of the transplanted skin could be traced, but the wound from that time made wonderful progress towards healing.

CASE 5 and 7.—A. H., 58, indolent ulcer on the leg of nine years' duration. At the time of grafting, five inches by three inches in size. Two small pieces of skin from the arm were applied to the sore, which grafts developed in about twenty-four days into islands of skin half an inch in diameter. The area of the wound was much smaller. My second operation on this woman, which was performed about a month after the first, was a failure, which I suppose was due to the fact that she did not lie in bed as she had done on the first occasion.

CASE 6.—This was one of the best cases.—F. H., 40, a woman of generally good health, had had ulcers on the leg for five years. There were three in the upper and middle third, the largest being two inches square, the smallest half an inch square (this received no new skin). Nineteen days after the operation the report is, "Smallest wound healed; the middle wound, originally two inches by one and a-half inch, is now less than an inch square; the largest wound has diminished by one-half; the grafts are one-third to half an inch in diameter." Six weeks later all the sores were healed.

CASE 8.—G. F., 5, a healthy boy, who had lost much skin from the front of his leg (middle third) by a contusion. When about two inches square the wound declined to grow any smaller, and two grafts were transferred from a groom's arm to the leg, but they did not adhere. The child was restless and did not lie in bed.

CASE 9.—J. K., 56, three very old ulcers on the leg of an underfed labourer. Four grafts applied to the sores all adhered, but the result is not given.

CASE 10.—H. L., 12. This case arose from an accident which almost severed the arm from the trunk. Four months afterwards, there being still a large extent of open wound, two grafts were applied, which adhered, and a month later two more grafts, which also succeeded. There is a note that they did not increase in size for a long time, but that eventually they did well.

CASE 11.—J. W., 60, a restless man, semi-imbecile, with an ulcer to which I applied grafts, which were lost in consequence of his inattention to the wound, and not resting the limb. They adhered well, and appeared at first likely to succeed.

CASE 12.—J. R. R., 11, had lost his thumb, metacarpal bone, muscles, and much skin with the aid of a gunpowder flask. Six weeks later, there being little prospect of a proper covering of skin for the wound, three grafts were applied, all of which adhered, and the wound healed some weeks later. In such a case I should in future repeat the graftings at intervals of two or three weeks.

In conclusion, I would remark that the proceeding causes little pain to the patient, that it often accelerates the healing process, and that a more flexible cicatrix may be obtained for a wound where there has been a great loss of skin than would result from leaving the wound to itself.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE sixth meeting of the session was held on Friday, 18th February, 1876, Mr. HAMILTON, President of the Society, in the chair.

UMBILICAL HERNIA.

Mr. CROLY said the specimen which he begged to lay before the Society was one of some interest. It was taken from the body of a woman aged 70 years, who was admitted to the City of Dublin Hospital on the 26th of January under his care. She suffered from umbilical hernia, and she had been suffering from the tumour (a cast of which he exhibited) for over 30 years. For the first 5 years the tumour was reducible, but for the last 5 or 6 years it became irreducible. It could not be ascertained how much of the tumour remained the full size of the cast, or how much went back. The patient was under the care of his colleague Dr. Purser, who treated her on several occasions for symptoms of strangulation, and on each occasion by proper treatment he was able to subdue the symptoms. On this occasion, however, the symptoms of strangulation could not be subdued by the ordinary method, and in consequence of this, Dr. Purser kindly asked him (Mr. Croly) to take the patient under his care. Being a recent specimen, he would not enter into the treatment of the case, or state why operative interference was not resorted to, but he would merely show the specimen. The cast showed a very large umbilical tumour, and during the lifetime of the woman the tumour was solid in some portions, and in other places it was resonant on percussion, so that it was diagnosed without any difficulty as a mixture of intestine and omentum. There was no mark of the umbilicus to be seen in any part. The woman lived over twelve days after her admission to the hospital, and died on the 7th January. On making the post-mortem examination, he made an incision along the axis of the tumour and dissected down. A matter of practical importance in these cases was the presence or absence of a sac, which had been so much questioned by some high authorities. He might mention that he did not think it would have been possible to perform herniotomy in the case without opening the sac that was in the centre of the tumour. In this case the sac was so much thinned or destroyed by the pressure of the tumour, that he might say there was no sac, but higher up the presence of a sac could be demonstrated. On opening the tumour he found that there were coils of the small intestine not only deeply congested, but greatly altered in appearance now. The intestine was positively livid and almost of a gangrenous colour when the sac was opened. The stricture was exactly at the umbilical opening and the tension was in the central line exactly above the umbilicus, for on freeing that point above, he was able to reduce the intestine. In addition to the coils of small intestine, there were in the tumour portions of the omentum, and, as he suspected during life, he found along with the omentum a portion of intestine in addition to the tight stricture of the upper part. Lower down in the tumour was a portion of the transverse colon, so that the tumour contained not only the coils of small intestine, but a portion of the transverse colon with a very large piece of omentum. There was a very large quantity of milky coloured fluid through the intestine, with recent traces of lymph in the tight portions of the intestine. He thought the specimen was interesting because of the comparative rarity of the umbilical hernia in the adult, the size of the tumour, the great thinness of the sac, that was capable of being demonstrated by the other parts of the hernia having gone in, by the state of the umbilicus as some writers laid down, and the seat of the strangulation being in the umbilicus, and in a piece of omentum contained within it.

SUPERNUMERARY THUMB.

Mr. CROLY then exhibited a second specimen, which, though small, was, he said, interesting. A boy about 18 years of age came under his care last week with a supernumerary thumb, the operation of removal which was generally performed in early life not having as yet been accomplished. The boy was, however, bound apprentice in a house in Dublin, where they refused to continue him in employment in consequence of the unsightly thumb. He (Mr. Croly) thought, before he performed the operation of removal, it would be well to get a cast of the patient's hand for the Museum, and this he had accordingly done, and now exhibited it to the Society. The two phalanges were very well developed, and there seemed to be an articulating surface, but on removing the thumb it was found that there was no regular joining, but simply a cartilaginous surface or proximal phalanx which played on its outer side.

Dr. MAPOTHER then read a paper on

TOPICAL BLOOD-LETTING.

which will be found on page 176 in the succeeding discussion.

The PRESIDENT said the communication of Dr. Mapother's, which was a most valuable one, gave them the proper indications as to the best ways of blood-letting. He (the President) was under the impression that they had given up the practice of topical blood-letting rather too much, while in certain cases of inflammation it was very useful, and it was therefore of importance to know the localities where they could employ depletion to the best advantage.

Dr. HENRY KENNEDY said he thought the Society was in-

debted to Dr. Mapother for bringing forward this, what he (the speaker) might call lost subject. He agreed with the President that it was a subject that they had overlooked and neglected as a whole. During his connection for many years with the Cork St. Hospital he had constant occasion to have recourse to blood-letting, and of the value of it—though it had been lately questioned—he could not entertain the slightest doubt, nor did that meeting, he presumed, entertain any doubt as to its value. He questioned Dr. Mapother's remarks with reference to the leeching of the abdomen. In some cases of typhoid fever of the very worst description, which was generally indicated by severe vomiting, he (Dr. Kennedy) had seen leeching over the stomach attended with good effect. Dr. Mapother had drawn a distinction between applying leeches to the abdomen and about the rectum. The same thing had occurred with reference to dysentery. He (Dr. Kennedy) never applied the leeches to the rectum, while he had applied them to the abdomen with a decidedly beneficial effect. While he agreed as to the importance of putting leehces as close as possible to the seat of the disease, he was inclined to question the exact rules which the author of the paper had laid down in these cases. As he understood Dr. Mapother, he spoke merely of veins. He (Dr. Kennedy) did not see why the arteries or circulation through them should not be altered by local bleeding. It was hard to understand while there were arteries as well as veins, why, at any rate, they should not be equally affected, and he would be glad to know why the author had referred to veins and not to arteries. He wished to mention that on one occasion he saw one of a flock of sheep suddenly take a fit, and it fell on the ground working violently, and in the middle of that fit a quantity of blood gushed out from the nose, to the amount probably of a pint or more, and after a few minutes had elapsed the animal gradually recovered and got on its legs and staggered away. Dr. Mapother had stated in his paper that such a thing did not occur in the lower animals; it certainly did, however, in that case. As he had before remarked, the Society was indebted to Dr. Mapother for his communication, for it was on a subject that had been greatly overlooked of late years. Many writers had entered into the theory of how local bleeding can act. The question was not, however—How local bleeding can act? but it was—Does local bleeding do good? To that he must answer in the affirmative.

Dr. THORNLEY STOKER said that he had considerable experience of one of the practices Dr. Mapother had alluded to. Dr. Mapother had referred to the method of puncturing the testes in cases of acute orchitis and epididymitis, and which Mr. Henry Smith and others had advocated. He (Dr. Stoker) was not aware that the practice was generally followed here, but he had adopted it for some years past, and he had used it in almost every case of acute inflammation of the body of the testes or epididymitis which had come under his care. It was plain that that practice might have a beneficial effect in several ways—not merely relieving the tension by incising the fibrous covering of the organ or by drawing the blood from the congested vessels, but by tapping the acute hydrocele which undoubtedly existed in these cases, or in most of them to some extent. The practice was in his opinion efficacious in all of the three ways. He had been in the habit of seeing cases of an acute nature, and it had been his custom to carry the puncture in some cases where the inflammation was not acute, and where, apparently, the epididymis only was involved—it had been his habit to puncture only the tunica vaginalis, and simply to draw off any serum that might have accumulated there. In all cases where he considered the body remained engaged, and where the inflammation was of a severe character, he had pushed the point of his knife into the testicle itself. He made four, five, six, or seven punctures, and he never found any ill effects result from that treatment, and he believed it afforded an amount of relief that no other plan of treating acute inflammation of the testicle afforded. He had resorted to other plans, but he was entirely in favour of the plan he had stated.

Mr. CROLY considered the subject one of very great practical interest. There were, he thought, two or three points which Dr. Mapother had omitted from his paper, but that probably arose from the difficulty one experienced in collecting all the facts connected with the subject. It so happened that that morning he (Mr. Croly) was called upon to puncture the ranine vein in a case of inflammation of the tongue, and as Dr. Mapother undoubtedly knew, this plan of treatment was described years ago by Velpeau, and gave great relief, if not to the tension of the organ, to the tension of the sub-lingua space, which was an invariable complication of this disease. With regard to the great danger which Dr. Mapother apprehended from jugular venesection, he (Mr. Croly) did not agree with him as to that, inasmuch as it was an operation that he had not only seen frequently performed, but he had performed it himself, and the risk, if they came to consider the effect of the venesection of the external jugular vein at the point at which they selected to open it, it was not held open by the cervical fascia, and the risk of the entrance of air was consequently not as great as might be supposed. At all events, practically they knew that the entrance of air into a vein was very rare, though it had undoubtedly occurred after the removal of tumours, where the veins were left in a patulous condition. With regard to the venesection at the scrotum, he did not agree with Dr. Mapother's views, because it was a practice that he (Mr. Croly) had himself followed with success. Many present remembered a case in which a student of that College, who, having what might be called the hæmorrhagic diathesis, applied leeches himself in a case of epididymitis. He (the speaker) had seen it produce great relief to the very congested portions of the veins of the scrotum, pointing out the necessity for bleeding in this region. He could not agree with his friend Dr. Stoker as to the action of the deep puncturing, because when they considered that acute hydrocele was outside the tunica albuginea, he could not understand how puncturing of the serous coat could relieve tension, because they hardly ever met a patient that suffered acute tension in hydrocele, and the relief of that fluid did not answer the purpose. He thought Sir Philip Crampton many years ago wrote a paper on this subject of topical blood-letting, and one of the places where that eminent surgeon was fond of applying leeches was the conjunctiva in ophthalmic cases—turning down the lid and applying the leech inside, instead of the ordinary plan of applying it on the temple. Leeches applied directly to the prostate gland were an extremely valuable mode of treatment. He had followed the plan of leeching the septum of the nose because he had strong convictions that in head affections it was the best mode of treatment they could adopt.

Mr. W. I. WHEELER said he could state from observation with regard to sunstroke the advantages of bleeding—in certain cases of sunstroke—those cases which they might call sunstroke having the premonitory symptoms described by Russell Reynolds. He (Mr. Wheeler) could not agree with Dr. Mapother in thinking that in renal congestion it would be useless to apply leeches for the purpose of affording relief to the kidneys or by any topical principle. If he (Mr. Wheeler) remembered rightly, in the paper of Professor Turner of 1859 he clearly showed that the vessels of the kidney anastomosed very freely, and consequently by acting on the vessels of the abdomen affected indirectly the vessels in the kidney. With regard to leeching over the mastoid process for inflammation of the eye and retinitis, it occurred to him that blood could be taken much more directly by the abstraction of blood through the angular veins, and the only objection to that would be giving the patient ecchymosis. He did not think that the vein which traversed the mastoid process was superficial enough to allow any leech to bite, and there were cases on record in which the vein which traversed the mastoid process passed from without inwards, and not from within outwards. He would like Dr. Mapother to explain how it was that leeching over the mastoid process would more directly take blood from the eyeball than leeching over the angular vein.

Dr. MAPOTHER replied, and said he was glad to find so many supporters of topical blood-letting, which the anti-venesection rage had thrown into undeserved neglect. Dr. Kennedy had seen good follow leeching of the skin of the abdomen in gastro-intestinal affections, butit was probably due to concurrent treatment, and the practice was at least empirical. He had in his paper distinguished the bleeding from arteries and veins. Dr. Thornley Stoker's experience of puncturing the testis for inflammation was valuable, but emptying the tunica vaginalis could scarcely avail much in cases of epididymitis. He had not alluded to glossitis, as the disease was rare, and opening the ranine vein only drained the under surface of the tongue, while incisions were most effectual by letting out blood and serum from the substance of the organ. Leeches on the conjunctiva were not nearly so effectual or convenient as puncturing the turgid vessels, and he had failed in getting leeches to bite the mucous membrance of the rectum. He agreed with Mr. Wheeler as to the angular vein being a capital site for draining the ophthalmic vein, but the frequent ecchy-

mosis and scar which resulted made it very objectionable. The opening for the mastoid vein was very large, and he found it constant in skulls, and it freely joined the skin of the region, where leeches might be applied.

CLINICAL SOCIETY OF LONDON.

CASE OF ACUTE ŒDEMA OF THE LARYNX

MR. PUGIN THORNTON related the case of a cabman who had been attacked with acute œdema of the larynx, and remarked that this was the disease which, followed by œdema of the lungs, proved fatal to the late Dr. John Murray. The cabman had gone to bed on a Saturday night at nine o'clock perfectly well, although over-fatigued from his work. Twice in the first two hours he had been obliged to change his shirt, waking up with it wet through with perspiration. He had then slept till the morning, when his breathing was slightly oppressed, and at breakfast he found swallowing difficult. Both respiration and deglutition gradually became worse, and on Wednesday morning he was sent by Mr. W. H. Evans, of South Hampstead, to Mr. Thornton, with the request that he would admit him, if possible, into the Hospital for Diseases of the Throat. On examination his epiglottis was seen to be an œdematous mass, and the arytenoid cartilages were observed to bulge out in the same œdematous condition. Mr. Thornton immediately very freely scarified these parts, and made the man encourage the bleeding by gargling as forcibly as he could with hot water. The scarification was repeated in about ten minutes. His breathing then, which but a short time previously had been extremely laboured, improved rapidly, and his face soon lost all lividity. He was able to take some milk from a spoon, and in an hour from that time, after being scarified again, he drank from a cup, having for many hours been unable to swallow the smallest quantity of fluid. From this time he made an uninterrupted recovery. On the first day only after his admission into the hospital did his urine present any albumen. The cause of the œdema was undoubtedly overwork, combined with the effects of extreme cold; for during the fortnight before the attack he had been day and night obliged to drive his cab with snow on the ground the greater part of the time, and had got only from four to five hours' sleep out of the twenty-four. He had never had syphilis, and was a temperate man. Mr. Thornton remarked that œdema of the larynx might arise in a mucous membrane perfectly free from inflammation, and that it did not, as is stated by some writers, always follow acute congestion. He instanced two cases bearing out this fact, one being that of a patient whom he had seen two hours after the commencement of the œdema in one arytenoid cartilage and at the root of the epiglottis, and the other that of a medical man whom he had attended a fornight previously, in whom, when he first saw him, the œdema had begun in the left arytenoid cartilage, vocal cord, and ventricular band of the same side. Mr. Thornton suggested that this disease should be classed in future in medical works under the heading of "Acute Œdema of the Larynx," and not ranged under "Acute Laryngitis," as heretofore.

DR. MURCHISON thought that exposure to cold was quite sufficient to produce the œdema.

DR. CAYLEY wished to know the temperature; he did not consider it possible to have "acute œdema" without local inflammation.

MR. A. T. NORTON said œdema at the entrance to the larynx was common enough in cases of phthisis syphilis, also in chronic ulcerations of pharynx, throat, and œsophagus, without any local inflammation. The least exposure to cold in such cases would cause the œdema; but as they were not accompanied by acute inflammation the œdema never extended into the cavity of the larynx, and therefore, though the sound of the respiration detected the presence of œdema, respiration was never obstructed. He did not consider the term "acute œdema of the larynx" applicable.

Mr. WILLETT had frequently seen œdema of the larynx associated with erysipelas of the face, and without any local inflammation.

Mr. THORNTON said in reply that there was only slight increase of temperature, and that he referred to simple œdema only, and not to œdema dependent upon other diseases.

CASE OF REDUCTION OF PARTIAL DISLOCATION OF THE ASTRAGALUS OF LONG STANDING.

Mr. G. BROWN read a paper on this case. The patient, Clara P., aged 16 years, accidentally slipped down a step about two weeks before Easter, 1874, and twisted her left foot. Previously to this she had nothing the matter with either of her feet or ankle-joints, except that she was always somewhat flat-footed. The foot was very painful after the accident, but, as it was thought to be nothing more than a "sprain," no medical advice was sought. On Easter Monday she took a long walk, after which she suffered great pain of the foot, and there was, the mother stated, a decided swelling on its inner side. Next day a surgeon was consulted, who said there was weakness of the ankle-joint, due to constitutional causes, and that its misshapen condition was in consequence of her being flat-footed. Several months elapsed; meantime the deformity became more marked, and the difficulty of walking greater. Towards the end of the year she was scarcely able to walk without assistance. Often the pain of the foot was so great as to prevent her sleeping at night. Mr. Brown first saw the patient on January 9th, 1875. On comparing the two feet there was apparent displacement of the astragalus forwards and inwards. The hollow which should exist between the internal malleolus and the scaphoid tubercle was obliterated by the head of the astragalus, which, at this point, was prominent. Over this projection the skin was tightly stretched. In front of the ankle-joint and on its outer aspect, where the head of the astragalus is usually felt, was a considerable depression. The tendon of the extensor proprius pollicis and the long extensor tendons of the toes were much contracted; the outer side of the foot was drawn upwards, and, in walking, the whole weight of the body was borne on the inner side of the foot. Power of extension or flexion of the foot was almost entirely lost. Reduction was effected in the following manner. The leg being firmly held by an assistant, the foot was forcibly extended; at the same time firm pressure was made on the projecting head of the astragalus, until the bone slipped into its natural position with a distinct snap. The two feet were then symmetrical, and a pad and bandage were applied. Next day the bone had again slipped out of place. Reduction was again effected, and a well padded side-splint with foot-piece applied to the inner side. The splint was kept on for seven weeks, after which the patient was permitted to walk with assistance. She made a slow recovery, but had how—thirteen months after the reduction of the dislocation—perfect use of the joint, and could walk long distances without inconvenience. Mr. Brown was of opinion that, when the patient twisted her foot, some fibres of the internal lateral ligament of the ankle-joint and the calcaneo-scaphoid ligament were ruptured. The head of the astragalus having thus lost its chief internal support, it was gradually forced forwards and inwards by the weight of the body, until the deformity became very marked, and the ankle-joint almost useless. Mr. Brown said that the case was of interest, not only on account of its comparative rarity, but as being one of a class of cases that frequently fell into the hands of "bone-setters," and by which these persons sometimes gained a great deal of credit at the expense of the profession.

Mr. PICK wished to know what apparatus had been applied to the foot. Any dislocation would have existed still, unless retained by supporting apparatus.

Mr. WILLETT wished to know the position of the os calcis with regard to the astragalus.

Mr. A. T. NORTON asked if anything had been noticed as to the walks, with the astragalus lying over the scaphoid, and the latter bone thrown back as far as the os calcis, as described by Mr. Brown, to walk would have been a difficult matter, and accompanied by great pain; and after such a dislocation of nine months' standing, he should have expected to see a considerable amount of absorption of the bones, whereas the foot was not at all deformed.

Mr. BROWN, in reply, said the patient wore no other apparatus than the splint. The astragalus was half-an-inch out of its position, and therefore it must have slipped from the os calcis. He thought the reason of the bone not being absorbed was that the dislocation took place gradually.

SCIRRHUS OF MAMMA: EXCISION: SUPPOSED CURE: DEATH AFTER EIGHT YEARS FROM CARCINOMA OF RECTUM AND FEMUR.

Mr. KESTEVEN sent a note, giving the sequel of a case of scirrhus of the breast reported in the sixth volume of the

Society's *Transactions* (April 23rd, 1873). After two operations, no recurrence of the disease had taken place for six years, and the case was regarded as one of complete cure, and seemed to support the view of the local nature of cancer. The subsequent history of the patient did not, however, bear out these opinions; for the patient died in the latter part of 1875, with cancer of the rectum and osteo arcoma of the femur.

Dr. CAYLEY and Dr. COUPLAND spoke of the rarity of secondary cancerous deposits in the rectum after removal of scirrhous breast.

Dr. GREENFIELD asked if the glands of the mediastinum or lumbar regions were affected.

PURPURA RHEUMATICA.

Mr. H. G. TREND read notes of this case. The patient, a youth seventeen years of age, had been out of health for some months. On April 6th, while engaged in cellar-work, a cork flew out of a soda-water bottle, and inflicted a deep incised wound, about two inches and a-half in length, on the outer part of the right forearm, which did not heal for a month. On May 23rd, he was attacked by well-marked tonsillitus; upon the subsidence of which, he was seized with painful swellings of several joints, preceded by a distinct rigor, and accompanied by purpuric patches upon the legs and arms. There was extensive sloughing of the upper portion of the left arm. After a protracted illness, he got quite well. The treatment consisted in keeping the patient well up with plenty of good nourishment, moderate stimulation, and perchloride of iron.

Dr. MURCHISON had seen similar cases, but not resulting from an injury. He asked if the pains were erratic, if hæmorrhage from any parts, and if the purpuric spots were raised. He related the case of a boy who had swelling of the knee, supposed to be rheumatic, but soon extravasation of blood took place beneath the skin attended with hæmorrhages from the bowels, gums, and kidneys. There was no evidence of specific fever in this case.

Dr. STEWART considered an eruption with rheumatism not uncommon. He had seen distinctly raised patches occurring for weeks in rheumatic cases, and he had termed them rheumatic erythema.

Dr. GREENFIELD considered that the case was one of scurvy. He also asked if the pericardium or heart had been affected—was the brain also affected. He had examined cases in which hæmorrhagic spots had existed on the brain without brain symptoms during life.

Mr. G. BROWN said purpura might occur with any lowering disease, and referred to the case of a boy suffering from abscess in the knee-joint, in whom the thigh was amputated, and in whom the surface of the abdomen from the umbilicus to the pubes became purpuric; the patient made a good recovery.

Mr. TREND, in reply, said the purpuric spots were not raised; the only hæmorrhage that had taken place was in the dysenteric motions, which extended over nine days; the rheumatic pains moved from joint to joint; and the perspiration was acid; there was no cardiac affection.

Dr. WATKINS remarked that in some cases of rheumatism under his observation, purpuric spots had appeared whilst the patients were treated with chloral hydrate, and had disappeared on withholding the drug.

THE weekly return of metropolitan pauperism shows the number receiving relief to have been 88,929, of whom 37,556 were in workhouses, and 51,373 out-door. Compared with corresponding weeks in 1875, 1874, and 1873, these figures show a decrease of 9,535, 18,382, and 28,473, respectively—a very satisfactory state of things.

THE mortuary question in the metropolis again cropped up at the weekly sitting of the Marylebone vestry, when a report was presented from the sanitary committee, calling upon the vestry, as the guardians had refused to receive and allow post-mortem examinations of bodies at the workhouse mortuary, to erect in the Paddington Street burial ground a post-mortem house, inquest room, waiting-rooms for witnesses, &c. It was resolved to forward the report to the guardians.

WEDNESDAY, MARCH 1, 1876.

LEGISLATION FOR THE HELPLESS.

POLITICAL economists tell us that the rules for securing the physical well-being of communities are simple, and when sought in a spirit of candour almost self-evident. To us it has appeared that the larger part of the helpless classes of the community stand greatly in need of efficient rules for securing their physical well-being. The blind, the deaf and dumb, the lame, the deformed, the idiotic, the imbecile, and other classes have, not only a claim upon our charity and sympathy to secure them from wanting the necessaries of life, but their physical well-being has secured legislative interference to rescue them from the gloom which might otherwise hang over existence. Upon turning to the legislation of the last ten or twelve years upon this question we were not a little surprised to find that the first Act bearing on the maintenance and education of the more helpless of the afflicted was passed in the reign of William IV. By the Act 4 and 5 Will. IV., cap. 76, sec. 56, it was enacted that relief given to, or on account of, any child under the age of 16 *not* being blind, or deaf and dumb, &c., should not be considered as parochial relief given to the parent; the effect of which is to enable guardians of parishes to assist in the education and maintenance of the afflicted blind and deaf and dumb *up to* 16 years of age out of the rates. This beneficent Act has since been followed up by numerous others, all bearing on the same, and which provides not only for the blind, and deaf and dumb, but for numerous other classes—as the lame, deformed, idiotic, imbecile, insane, &c.

These several classes are more numerous than is generally supposed; the cripples alone number about 100,000, while the blind are something over 30,000: of these there are only 41 under 40 years of age in workhouses, and 466 above 40, all of which might be far better cared for than scattered about among the pauper institutions of the country. In the census of 1871 there were in England and Wales, 29,452 idiots and imbeciles. This number is admitted to be 25 per cent. below the mark,

showing a total of 36,835, or 1 in every 621 of the population. At that time there were 7,976 of these in union workhouses, and of the whole estimated number, there were only about 1,300 under any kind of training besides the inmates of the Caterham, Leavesden, Clapton, and Hampstead asylums, where a good beginning has been made, but where they scarcely receive all the training and supervision they specially require, and where they often meet with much unkindness. In lunatic asylums they are more out of place, imbecile children particularly so. The Lunacy Commissioners have frequently testified to the fact, a result of extended experience and observation, that the association of idiot children with lunatics is very objectionable, and injurious to them. They write: "It is always to us a painful thing to see idiot children, whose mental faculties and physical powers and habits are capable of much development and improvement, wandering, without object or special care, about the wards of a lunatic asylum." It is quite certain that the condition of a large proportion of youthful idiots can be altogether altered and improved by careful training, and a persevering endeavour to develope dormant powers, both physical and intellectual, that argument upon the subject is quite superfluous.

The most important among institutions for the imbecile supported by private benevolence is the Earlswood Asylum. Even this has outgrown the capacity of individual charity, and the management of its elections has in great measure passed into the hands of those who contract to get candidates in for a given sum, and abuse their authority to make the thing pay by begging, exchanging, and selling votes. In consequence of the evils of this humiliating traffic in votes most of the cases admitted into the asylum are not the most distressing, nor those who stand most in need of the benefits of good training. Its direst effect is that out of 594 inmates of both sexes, nearly four-fifths belong to the class already amply provided for by existing Acts of Parliament—paupers—and for whom this charity was never intended. Another evil of the voting system is that only about one-fourth of the whole number is received at that age when they are most capable of education. There are only 35 between seven and ten, and 122 between ten and fifteen years of age. A most objectionable rule, intended to operate against this small number, *excludes after five years*, and thus subjects parents and friends to another exhausting and expensive canvass among 13,000 subscribers, just at a time when the training is beginning to tell upon the mental and physical condition of the child. This is scarcely creditable to a well-appointed charity, receiving £30,000 a year from the benevolent. The consequence, however, is that the most liberal givers are more frequently repelled than attracted to the work of improvement, and those who originally subscribed to get in a case refuse to do so as soon as the object has been attained, and where the benefited are all treated as if they were paupers, the whole burden of their support falling upon the institution, and although the families of some of them are often able to share in the expense of maintenance. The original outfit of institutions for this special class—that is, the heavy expense of buildings, &c.—should be provided for by the Government and paid for out of the rates, but the cost of maintenance and instruction should be apportioned in such a way as may be made to afford greater relief to the better or middle classes, who would gladly pay their quota in order to be relieved from the anxiety and burden of an imbecile member, and with the hope of the child being returned in an improved state.

But quite apart from these considerations, this class of afflicted persons have the strongest possible claim upon the national funds, and therefore efforts should be made to bring into force Acts of Parliament expressly passed to benefit them to the utmost extent. The mode of effecting this would be by asking for a conference of guardians, Metropolitan Asylums Board, district managers of School Boards, and the several committees and subscribers of charitable institutions. These bodies should also be brought before or in communication with the Local Government Board. This could be done by the aid of deputations, by circulars, &c. Should these means fail, application must be made to Parliament to give increased powers for working the Acts, so as to cover the whole of the afflicted classes, and effect the greatest possible good for them. "The Metropolitan Poor Act, 1867," gives power to erect asylums and schools, but this only applies to the metropolis; if it were found, however, to work well, its provisions should be extended to counties, or to unions of counties, or dioceses, as might be found most convenient to work. The late Commissioner, Mr. Lutwidge, who was murdered by a lunatic, was at the time of his death engaged in the preparation of a draft bill which would have facilitated the establishment of training schools and the regulation of idiot asylums, releasing such asylums from the stringent regulations of the Lunacy Act 8 and 9 Vict., cap. 100.

The capitation grant of 4s. per week allowed for idiots in lunatic asylums should be extended to all institutions where they can receive proper care and training. The magistrates of Warwickshire have erected on the grounds of their County Lunatic Asylum a building for two hundred idiots, but the guardians refuse to use it, although the capitation grant is allowed for them as well as for lunatics in the larger asylum. The Government grant would doubtless be extended to all properly conducted institutions, whether supported out of county rates or by voluntary contributions; and institutions supported by private benevolence might greatly help on the work by grouping themselves together in classes, or by even some moderate form of union or central body which should adequately represent them, and which would consider the great questions affecting the blind, the deaf and dumb, the imbecile, and other classes, and how best the large charitable funds placed at their disposal could be applied in securing the greatest amount of good for the greatest number; that is, in giving the highest training and education to those adapted for it, and in grants of scholarships, &c., to the most deserving. If the institutions were made of a high character and very efficient, then the blind and those afflicted belonging to the upper and middle classes might be sent to the same schools and an arrangement of classes made between the schools. What is much required is that the afflicted of each class should be dealt with as a whole and as parts of one system. Under any circumstances, however, it cannot be considered more demoralising to accept *legal relief* than to have to expose one's domestic troubles and poverty to 13,000 subscribers.

THE EPIDEMIC AT EAGLEY.

THERE are few things more memorable in the annals of medical discovery than the circumstances by which medical men gained a clue to the hitherto obscure cause of those outbreaks and sporadic cases of typhoid fever that were continually occurring in some parts of the country. Ever since then epidemics of this fever have very properly attracted unusual interest, not only from the profession but from the public; and it is now one of the triumphs of medical science to trace these epidemics to their original source, to at once arrest the conditions which give rise to them, and to prevent their extending beyond the district originally invaded, or attacking any more persons than those originally attacked. The force of these remarks is amply illustrated by the Eagley epidemic, the severity and sudden outbreak of which showed that the system of the individuals stricken down was infected by a poison which must have been of local origin, and by which they must have been almost simultaneously affected. With respect to the percentage of the population attacked and the fatality of the disease, this epidemic is about as bad as any that has recently broken out. The earliest case was brought before the notice of the local authorities on Wednesday, the 9th of February, and before the following Saturday evening there were between eighty and ninety persons confined to their beds with fever—a form of typhoid fever, clearly traceable to milk contaminated with water "so foully polluted as to render it little better than liquid sewage." The epidemic extended as far as Bolton, and up to the 19th of February, six fatal cases had occurred. Eagley is a small village which lies in a valley about two and a-half miles from Bolton. It does not contain more than 500 inhabitants, and the majority of these are employed in some tape and cotton-thread works which are built on the stream running through the valley and passing by the lower part of the hamlet. A question here arises whether the circumstance last mentioned could have influenced in any degree the severity and spread of the epidemic, as it is natural to suppose that a population confined within narrow limits, and for the most part engaged in manufacturing pursuits, would be more obnoxious to the effects of an epidemic of this kind than one engaged in agricultural pursuits.

According to the local newspapers, some of the cases were of a hybrid nature, and were attended with colic, tremor, pains in the limbs and in the back, swelling of the tongue and of the eyes, &c. Moreover, we have heard that those persons who drank large quantities of the contaminated milk at a time suffered from severe colic, coming on in two instances almost immediately after they had taken the milk, and attended with copious purging. Those who had only taken a small quantity of the milk did not get off so easily, their cases presenting the form of pure typhoid in all its stages, "while in a few modified cases there was pyrexia which lasted three or four days, and then passed off with profuse perspirations." In many instances, however, the disease appears to have assumed a mild type, the large percentage of the population attacked showing, as we might expect in respect of a fever which is only indirectly contagious, rather the extent to which the vehicle of the poison was diffused among the inhabitants of Eagley than the virulence of the disease himself.

The chief interest attached to this, as to all similar epidemics, lies in the causes which gave rise to it, and fortunately it was not long before those causes were found out. It was soon discovered that in every case the sufferers had been accustomed to drink milk from one particular farm, while those who had not been in the habit of drinking that milk, although living in the same house, invariably escaped the disease. A visit to this farm further showed that the milk-cans were always washed with water contained in two large tubs in the yard—that this water was supplied by a brook which runs by a mill now in course of erection—and that, from no accommodation having been made for the men employed in erecting the mill, excrement had been left on the banks of the stream, and from thence washed into the water at every fall of rain. As there had been no analysis made of the milk retailed before the outbreak, nothing could be known of the condition of that which actually caused the epidemic, but from the above facts, it is evident that the outbreak is not to be attributed to the milk itself, as it came from the cow, but to the water with which it may have been adulterated, or with which the milk-cans were washed out. The milk, then, had evidently become contaminated with sewage matter. It would seem also that its condition had attracted the notice of those who consumed it, for our correspondent was informed that the milk had been for some time previous to the outbreak of an inferior quality, soon turning sour, and having a fetid odour and greenish appearance. Nor does it appear that the water which had contaminated the milk had become infected with any specific poison, as no preceding case of typhoid fever had been known to occur. An examination, however, of the water in the tubs above mentioned, left little doubt as to its sewage contamination, inasmuch as it contained large quantities of free ammonia, albuminoid ammonia, and chlorine. But as far as the etiology of typhiod fever is concerned, the great question is whether this sewage contamination was, or was not, of a specific nature. In most outbreaks of this kind the water has been found to have been polluted with fever evacuations, and a more strict investigation will be necessary before it can be said that such was not the case in the Eagley epidemic.

At all events, this and similar outbreaks show the necessity of ensuring the purity of all water that is used in dairy farms, and on the premises of all milk-vendors. That a whole village should be half-poisoned by milk that had, through carelessness, become polluted with water taken from a dirty brook, is scarcely consistent with the efforts which the Government and the profession are making to secure the public from such calamities as that of the Eagley epidemic, nor with the vast and complicated machinery by which sanitary reformers seek to attain the laudable object they have in view. Milk is an article the consumption of which is very large, and, unlike other kinds of food, most of it is used in the raw state—that is to say, without undergoing that purifying process which is supposed to result from boiling or baking any matter that is impregnated with the germs of disease. It is therefore to be hoped that before long all sources of milk-

supply will be placed under strict sanitary inspection, and that we shall hear no more of typhoid epidemics originating in the defective sanitary arrangements of dairy farms.

Notes on Current Topics.

Advice to Mothers.

Last week we commented upon the circulation of a circular relating to the sale of works by Mr Pye Chavasse, "Advice to a Mother," and "Advice to a Wife," &c., &c. It is gratifying to learn from Mr. Pye Chavasse that it was without his knowledge and consent. The name of a second-hand bookseller was attached to the circular, and no books were referred to but those of the author above mentioned. Such a method of advertising is calculated to do an author a serious amount of mischief, at least so far as professional position is concerned, and we trust that for the sake of the able writer of the works the bookseller will discontinue his method of advertising medical works.

Homœopathic Faith.

The *Chemist and Druggist* suggests that investors in the Co-operative Bank, and others who find a lack of exercise just now for their inordinately developed faculty of faith, might practise on a morsel which the *Homœopathic Review* quotes with all due solemnity from a journal of parallel persuasion in America. Dr. Dunham, who must be a homœopath of some note in the United States, for he has been selected to preside over the Homœopathic Convention was smitten with a severe cardiac rheumatism some few years since, which compelled him to relinquish practice, and was regarded as incurable by practitioners of both schools. Having thus duly consulted the astrologers, the magicians, and the soothsayers, Dr. Dunhan turned at last to the homœopathic Daniel, a Dr. Hering. The oracle spoke and said that if *Lith. carb.* was not the remedy he did not know what was The rest of the story we will not interfere with, except to explain to any reader who may not happen to be sufficiently "up" in trituration that the "third" would contain 1 part of the medicine with a million of sugar of milk. "The patient now returned to his home, and not being able to find the desired potency of the *lithium* he procured the third trituration, and attempted himself to triturate to a higher degree. The medicine having been placed in the mortar with the requisite sugar of milk, he began the trituration. It was not long, however, before the exhalations from the triturating drug began to manifest themselves, and the patient succumbed to their influence, *lying for some time in a semi-unconscious state.* The recovery from this latter seeming complication was slow, but resulted in most complete recovery from his cardiac disease, without farther medical aid, thus illustrating the wonderful efficacy of the truly homœopathic remedy, and the care requisite to its selection."

This is nearly as good a story as that told by the same journal some months ago, of a lady who was brought strongly under the influence of some almost inert medicine by sitting in the same room with her husband, who had mixed a little of the drug in his bath.

Inspection of Dairy Farms.

Mr. Sclater-Booth has stated that the question of wholesale poisoning by milk adulterated with water from polluted sources will receive his attention. On more than one occasion typhoid fever attacking more than a hundred persons has been traced to a single dairy farm, and we know not how far the disease might spread if large London dairies, or ff the dairies of other large country towns should become a source of typhoid fever poison without being at once detected. For generations the frequent diarrhœa of infants has been in perhaps the majority of instances put down to faulty milk, and the cause was then supposed to be the sourness of the milk, but now we can trace its rapid fermentation to the presence of putrid material—its adulteration with water from polluted sources. Even at the present time an epidemic of fever, the effect of a sewage adulteration of milk, is raging at Eagley, having attacked 150, and destroyed eleven persons out of a population of about 500. Surely the people will never be satisfied until they receive some guarantee that milk, an article of diet consumed daily by every individual, shall be free from poison, and this can only be obtained by the periodical inspection of dairy farms.

Small-pox in a Prison.

Mr. E. S. Bignold, the Norwich City Coroner, held a second inquest in Norwich Castle last week on a prisoner named Joseph Mace, who was committed on the 25th of January at North Walsham for twenty-one days on a charge of stealing fowls, having succumbed to the outbreak of small-pox which has recently occurred in the prison. The clothes of the deceased were burnt after his death, and his body was interred immediately after the inquest, which resulted in a verdict of "Death from natural causes." There are still twelve prisoners suffering from the disease in the prison.

Weighing a Ray of Light.

Our morning contemporary the *Standard* reminds us that Mr. Crookes did not really "weigh a ray of light," but what he did was to measure the mechanical force exerted by a ray of light impinging on a given disc. This he measured by attaching the disc to an arm, and that again to spun glass. The repulsion of the disc by the light involved a certain torsion of the spun glass, and the force necessary to produce that torsion could be, and was, ascertained and expressed in weight. But it by no means follows that because the mechanical force of a ray of light may be expressed in terms of weight, the ray of light is thereby weighed. Weight with us means the amount of force by which the bulk of the earth attracts substances towards itself, and we have not as yet any demonstration that light is so attracted. At any rate, whether light is in this sense ponderable or not is a matter left wholly untouched by Mr. Crookes' experiment. A familiar instance of the distinction between weight, and force expressed in terms of weight, will make this perfectly clear. The atmosphere which surrounds the earth has weight—*i.e.*, it is held to the earth by the attraction of the bulk of the earth. We can weigh it as a whole, or we can weigh it by the pint or the gallon. The barometer tells us that

its weight as a whole on the surface of the earth is about fifteen pounds to the square inch. Set it in motion and it is wind. Its weight is not affected by this, as the barometer shows, but its motion involves a mechanical force which the anemometer finds for us and expresses in terms of weight, so that after a heavy gale we may read that the pressure of the wind varied from ten to fifteen pounds on the square foot. This latter is the kind of force measured by Mr. Crookes, and to call it weight induces a confusion of thought.

A London Fog and its Results.

The metropolis can boast of few winters when fogs have been less prevalent than the present. The usual season for these unwelcome visitors, November and December, passed with scarcely a sign of their unpleasant consequences, and when even January had gone, and the weather, though cold, was bright and cheerful for London, citizens congratulated themselves upon the result. But such were doomed to disappointment: Friday, the 11th of February, was ushered in—in fact, passed its twenty-four hours—without a sign of the lifting of one of the densest fogs that has frowned upon us for years. Few whose misfortune it was to be in town, and had out-of-door duties to perform, will forget its effects upon their respiratory organs, and alas! many families are now in mourning for friends who, but for that one fog, would in all human probability have been in their midst at the present moment. We know personally of several deaths attributable to no other cause, whilst the Registrar-General's statistics show most unmistakably its effects. That week the death-rate rose from 24 to 30 per 1,000; 49 fatal accidents occurred; whilst to diseases of the respiratory organs no less than 622 deaths were referred as compared to 465 in the previous week, 410 resulting from bronchitis, and 118 from pneumonia. We have often heard friends from the country express a desire to see a London fog, and on the present occasion an American *confrère* was in our society imbued with the same notions. Although most unusual in February, our friend was gratified with the wished-for sight. He *guesses* he will defer visiting London again until the season is a little further advanced.

A New County Hospital for Lincoln.

Some time since we mentioned the fact that the present hospital was inadequate for the requirements of the city and county of Lincoln, and that plans and tenders had been laid before the committee, and subscriptions invited of the public to defray the cost. Last week a special meeting was held, at which an amended scheme was agreed to and the tender of £21,000 accepted for the building, which with the architect's commission, improved heating apparatus, and other items, will bring up the total to nearly £23,500. To meet this expenditure £21,600 has been promised by subscriptions, leaving but a small balance to free the new hospital of debt. The building will, we understand, be proceeded with at once.

Medical Relief in Scotland.

On the 23rd ult. a deputation of Scotch members of Parliament waited upon the Chancellor of the Exchequer to make a representation on the subject of the Government grant for medical relief in Scotland. Mr. M'Laren, who introduced the deputation, said the most important point was that whereas England got for medical relief a grant in all of £271,000, Scotland had only £11,000. He contended that Scotland was entitled to a larger grant. The Chancellor of the Exchequer said the deputation had raised a much wider question than the adequacy or inadequacy of the grant to Scotland. It should be recollected that if they applied the principle upon which the English grant was given, they must also apply the conditions attached to it. If it was the desire of members connected with Scotland to reopen the question, he was quite prepared to undertake the task, in conjunction with the Lord Advocate and the officials of the Board of Supervision in Edinburgh.

The Malay War.

A supplement to the *London Gazette* of Tuesday week contains various despatches respecting the operations of the Naval Brigade in the Malay Peninsula. For nearly a month the men had nothing to eat except preserved meats, supplemented occasionally by wild buffalo, but no vegetables or bread; they were often wet, and frequently had to wade through mud and water over their waists; for three days, in advancing to Kinta, they had to pass through dense jungle, above which the sky could not be seen, and for ten days they had no cover of any kind, but slept in the "open." Their immunity from disease on the march is attributed to the fact that they had been supplied with waterproof sheets.

The New Library and Museum of the Royal College of Surgeons of Ireland.

The building of a new library and museum to the Irish College of Surgeons, which has been so long in contemplation, was commenced some weeks since, the contract having been signed by the President and Council for the carrying out of the works within one year at a cost of £5,000. An unfortunate hindrance presented itself on the threshold of the undertaking which rendered it necessary to stop the works. The College is built on a piece of ground which was formerly a burial place of the Society of Friends, held by them from 1687 to 1805 for this purpose. At the latter date it was leased to the College, subject, however, to a covenant that a certain space containing the remains should not be dug up under a penalty of £2,000. For seventy years this space has remained without buildings, and this covenant had been long since forgotten until recalled to recollection by the inauguration of these works. It was necessary for the College to obtain the authority either of the representatives of the original lessors or of the Managing Committee of the Society of Friends before they could proceed further; and we have gratification in learning that after a conference upon the subject the necessary permission to proceed with the works has been granted under certain provisos for the respectful removal and reinterment of any remains which may be found within the same space.

The Metropolitan Asylums Board.

At the meeting of the Board on Saturday last, after the disposal of some routine business, the subject of main-

tenance of the various lunatic hospitals, and asylums under the Board's jurisdiction came on for consideration. The expenditure was estimated in advance for the half-year to Michaelmas, 1876, and the amount of precepts which will be required to be issued to the several metropolitan parishes to meet such expenditure was stated. The loan account and interest for the half-year will absorb £22,600, and office expenses and law charges £2,300; maintenance at the Leavesden Asylum, £20,600; Caterham Asylum, £23,000; Hampstead Asylum, £6,500; the Clapton Asylum, £6,500; Homerton Hospitals, £7,400; and Stockwell Hospitals, £5,250; being for maintenance account (5,030 patients), £32,775 15s., and common charges account £61,484 5s. — total £94,260. To meet this, the committee propose that the managers should raise by precept on the parishes an aggregate of £105,120, which will enable them to meet any demands which may arise in the event of the boys being maintained on board a training ship during the half-year. The report and estimates were adopted by the Board.

On the reports from the various asylums and hospitals being presented, attention was called to the increase of typhus fever cases received into the Homerton Hospital, chiefly from the district of Whitechapel.

During the week, out of eleven cases received, eight had been from that district, and the health authorities were doing all they could to ascertain the causes, and provide, if possible, remedies.

Excerpta Medica Redicula.

We clip the following advertisement from the *Dublin General Advertiser*:—

——'S WORKS.

NO MONEY REQUIRED UNTIL CURE IS EFFECTED.
NO MEDICINE OF ANY KIND PRESCRIBED.

	s.	d.
Farm Stock and Crops (Potato blight included)	21	0
Lunacy	45	0
Rheumatism	45	0
Married Woman	100	0
Scurvy	25	0
Hernia	12	6
Epilepsy	45	0
Sore Eyes	10	6
Consumption	45	0
Paralysis	45	0
All Diseases in Children	1	0
Errors of the Solar System	0	6
Darwin Confounded	0	6
Every Man his own Doctor	1	0

The above can be had, post free,
From Charles ——, Kilfinane, Ireland.

It conveys a neat compliment to our better halves to set down that the philosopher who undertakes to cure "without medicine of any kind" the errors of the solar system for the small charge of 6d. and to confound Mr. Darwin for the same small sum, finds that he cannot make the cure of "Married Women" pay a at less fee than £5, even although he can undertake the whole nursery for a shilling.

County Infirmaries in Ireland.

Neither Mr. Gibson's nor Mr. Meldon's Bills, to which we have already referred, have yet been laid on the table of the House of Commons. Mr. Gibson's, it will be recollected, proposes to throw open the surgeoncies of Irish County Infirmaries to all registered practitioners, and we anticipate that, being obviously fair in policy and indisputable in principle, it will not be opposed by the Irish College of Surgeons, who now possess the exclusive privilege of licensing surgeons for these institutions.

Mr. Meldon's Bill will endeavour to take the control of the infirmaries out of the hands of the present Board of Governors, and to relieve grand juries of the grants for their maintenance, to vest the management in a committee of Poor-law guardians, in addition to the life governors and annual subscribers, and to throw the public grants to these institutions upon the poor rates, and not, as heretofore, upon the grand jury cess. He will, we understand, also ask Parliament to assent to the granting of superannuation allowances to infirmary surgeons, a most necessary and reasonable provision, and for the sake of which we should wish the Bill to pass.

We look with the greatest apprehension upon any measure which will deliver over the special surgical hospitals of each Irish county to the Poor-law guardians, whose ideas of good surgery are usually clouded by their desire to save a half penny in the rates at any cost of efficiency or of advantage to the sick poor. They have, moreover, an hospital of their own, and they will assuredly not see the distinction which exists between infirmary patients and workhouse paupers, or recognise the necessity for maintaining a special surgical hospital in their locality.

We have two good reason to know that guardians in general are of opinion that "pass-muster" doctoring is quite good enough for the poor, and the cheaper it is the better, and—in our opinion—it would be preferable to close the doors of county infirmaries altogether than allow such a principle to pervade their management. It is, however, certain that the County Infirmary System of Ireland greatly needs reform, and that these institutions are suffering seriously from their unsatisfactory state of organisation, a condition, we are bound to say, due not a little to the neglect of some of them by their medical officers.

Ozonic Ether in the Treatment of Scarlet Fever.

The Central Board of Health having received from the Local Board of Health for the city of Melbourne copies of certain notes, by Dr. Day, of Geelong, on the use of "ozonic ether" in scarlet fever, have directed a copy of the same to be sent to each local board of health and registered medical practitioner in the colony, the marked success which has attended this treatment in Dr. Day's hands, not only in the recovery of the patient, but in the prevention of the spread of the disease, rendering it, in the opinion of the board, very desirable that it should, at the present time, be generally known.

Dr. Day's paper gives notes of the treatment of fifty-one cases, some of them resident pupils in ladies' schools, and in all of them he records a "good recovery," while in nearly all the infection was prevented from spreading to the other children or persons in the house, the exceptions being cases where this treatment was not adopted at the outset. The treatment adopted by Dr. Day was simply

having the whole surface of the body well rubbed over three times a day with a mixture of ozonic ether and lard, in the proportion of one part of the ether to eight of lard; this treatment being continued for about three weeks.

Dr. Day claims that the scarlatinal poison, as it escapes from the body, is at once destroyed, the beneficial action being purely chemical. He concludes that ozonic ether does not contain a particle of ozonic ether, but is in reality, a strong solution of peroxide of hydrogen in ether, a substance with a remarkable power of destroying zymotic poisons. He relies upon this powerful oxidiser and disinfectant in a concentrated form to destroy the poison germs of both scarlatina and small-pox as they are given off from the surface of the body. It has been said that scarlatina is most infectious during the process of desquamation, and it appears reasonable to suppose that the poison may be destroyed as it emanates from the body but the throat and the respired air are also a frequent source of infection, and doubtless also the excretions.

By the proper use of disinfectants and by very simple precautions the spread of scarlet fever might be limited, or perhaps even prevented, and the disease be absolutely eradicated, but it will be a long time before the people will understand and carry out these precautions. Whether ozonic ether is to be the chosen disinfectant remains to be seen.

The University of London and Musical Degrees.

A MEMORIAL to the Senate of London University, asking that degrees in music may be rendered available by that body upon a basis of sound general culture, has just been presented by the Council of Trinity College, supported by the signatures of Sir Julius Benedict, Sir Michael Costa, Sir John Ross, Sir George Elvey, Mr. Arthur Sullivan, and many other leading musicians.

Action of Light on Selenium.

On Friday week Mr. C. W. Siemens, F.R.S., delivered a discourse on "The Action of Light on Selenium." He said that, while Newton laid down incontrovertible principles regarding the nature of light, it has been reserved for physicists to prove the effect of light upon solids. One of the most beautiful illustrations of the permanent effects of light upon solids is furnished us through photography. Another effect is rendered visible by phosphorescent salts, which, when acted on by light, continue to glow in various colours for a length of time when taken into a dark room. Mr. Crookes had shown experiments illustrating the mechanical action of light on solids. It is, too, light that breaks up the carbonic acid in the leaves of plants in order to separate the carbon. Carbonic acid may be broken up by heat; but at a temperatuae of 2,500 deg. C., which would destroy all vegetable organisation. The influence of light on selenium makes known another action—an action which regulates the extent to which it is an electrical conductor. The history of the discovery is briefly this. Mr. May, a telegraph clerk at Valencia, noticed that a stick of crystalline selenium, such as had been used for some time in telegraphy where high electrical resistance was required, offered considerably less resistance to a battery current when exposed to light than when kept in the dark. The statement was received with some incredulity. Could it be possible that the mere superficial action of light upon a solid substance could so change instantaneously its internal condition as to open among its particles flood gates for the passage of the electric current, to close again upon the removal of the light? The question has within the last twelve months been made the matter of independent inquiry by Dr. Werner Siemens in Germany, and Professor Adams in England. By different methods these two observers have arrived at results which agree in most points of fact, though they somewhat differ in the deductions they draw from them. Selenium, an elementary body discovered by Berzelius in 1817, is placed by chemists in the border territory between metals and metalloids, and it does not seem to be amenable to the laws governing either of these natural groups. If melted it presents a brown amorphous mass of conchoidal fracture, which is a non-conductor of electricity, but if a stick of this amorphous selenium is exposed for some time to the heat of boiling water it assumes a crystalline fracture, and when again inserted in the galvanic circuit it is found to be a conductor of electricity. Experiments show the selenium under examination to be in a form in which the surface action produced by light can produce its *maximum* effect. For example, two spirals of thin wire (iron or platinum) are laid on a plate of mica in such a way that the wires lie parallel to one another without touching. While in this position a drop of fluid selenium is made to fall upon the plate, filling the interstices between the wires, and before the selenium has had time to harden another thin plate of mica is pressed down upon it so as to give firmness to the whole. The two protruding ends of the spirals serve to insert this selenium element in a galvanic circuit. Mr. Siemens calls this disc his "sensitive element." The whole arrangement is no larger than a sixpence. Its action was shown in this way:—It was placed in a galvanic circuit, at one end being a Daniell's cell, and at the other a delicate index galvanometer. The "disc" was first enclosed in a dark box; the circuit was "made" but no electricity passed through—no movement of the index was seen. The "disc" was then exposed to light; still no action was apparent. Another disc was taken that had been kept in boiling water for an hour, and gradually cooled. In a dark box it gave a slight passage to electricity as indicated by the index, but as soon as the light was admitted the index registered a great passage of electricity. Another disc heated to 210 deg. C., and allowed to cool, was then used, and a greater action still was apparent with this. The basis of the change in condition seems to lie in the fact of the extent to which the selenium is heated, for when again allowed to cool its behaviour depends on the extent to which it has been heated. The effect of different parts of the spectrum on a disc shows that the actinic ray produces no effect, while the influence increases as we approach the red end. A selenium photometer enables us to compare the relative effects of two lights in affecting the conditions for the passage of electricity. At the end of the lecture an interesting little apparatus was put at work, a selenium "eye"—a small hollow ball, with two apertures opposite to each other. In one is placed a small lens, 1½in. diameter, and at the other a "disc." The disc is connected with a Daniel cell and a galvanometer, and this represents the retina. There are two slides, which represent the eyelids. The action of

light on the disc is indicated on the galvanometer. Not only was this shown to be sensitive to white light, but sensitive in different degrees to different colours. Mr. Siemens said it would not be difficult to arrange a contact and electro-magnet in connection with the galvanometer in such a manner that a powerful action of light would cause the automatic closing of the eyelids, and thus imitate the spontaneous brain action of blinking the eyelids in consequence of a flash of light. To physiologists this analogy may be suggestive regarding the important natural functions of the human frame.

Nulla and Bona Fide Certificates.

THE position taken up by the University of Dublin with regard to sham certificates in Ireland is exciting much interest in the profession. Dr. Laffan, of Cashel, writes to Professor Haughton, thanking him for his assault on that vicious system. Dr. Laffan states that it has long been felt to be an intolerable grievance by regularly educated members of the profession. Few indeed, he thinks, will attempt to deny that it is a great injustice, that men who were engaged behind counters, when they were supposed to be attending lectures, should nevertheless be permitted to enter the lists on terms of the most perfect equality with those who have received a complete medical training.

IN the House of Commons on Friday last, the Home Secretary stated that the Vivisection Report would be in the hands of members as soon as it was free of the printer.

IT is announced that after the year 1877 candidates for the diploma in Dental Surgery of the Royal College of Surgeons will be required to pass a preliminary examination in arts similar to that which is at present undergone by students of medicine.

THE *British Medical Journal* announces with amusing *naïveté* that the proceedings of the Surgical Society of Ireland, "which heretofore have only been published in our own (the *B. M. J.'s*) pages and those of the MEDICAL PRESS," will appear in a separate form. The fact is that nothing but the briefest epitome of the proceedings of the Society have ever appeared in the pages of our contemporary, whereas the official reports in full have for forty years been published exclusively in our own pages. In any case the announcement is quite premature.

THE trustees of the late Robert Wilson, M.D., have advertised for applications of candidates willing to travel in Western Asia, or Eastern Africa, or Northern Africa, making observations of which a report is to be transmitted, and collecting antiquities and objects of interest. The allowance fixed by Dr. Wilson for travelling expenses is at the rate of 16s. per diem. The candidate selected must be a Graduate in Medicine of the University of Aberdeen, and under twenty-eight years of age.

ON Thursday, at the Liverpool Police Court, before Mr. Raffles, stipendiary magistrate, Captain Gourley, of the British ship *John Peacock*, was fined £30 and costs for having failed to provide or cause to be kept on board that vessel a sufficient quantity of antiscorbutics and medical stores. In consequence of the want of these, the greater portion of the crew were attacked by scurvy while the ship was on a voyage from Bassein to Liverpool. The prosecution was instituted by the Board of Trade.

A GALWAY newspaper reports the death of a young man who fell, and the pocket of his coat, in which he carried a file, having got under his back, the file went through him. He was conveyed to the County Infirmary, where *a magnet was provided of sufficient power to attract a large anvil*, but proved useless. It is further stated that on examination of the body, it was found that a portion of the file had gone clear through the spine between the second and third lumbar vertebræ, an observation which looks as if the magnetic notion had its origin in the brain of a medical practitioner. It would be instructive if we were informed as to the exact weight of the anvil, "large" being an indefinite term, and it cannot but be regretted that the Arctic Expedition had started too soon to convey the patient to the North Pole, where, no doubt, a still larger anvil would be "attracted." By the way, it may not be inappropriate to observe that the County Infirmary is the Clinical Surgical School, *and the only one* of the Queen's University graduates who take their education in Galway.

THE QUEEN'S UNIVERSITY AND THE PRESS.

UNDER this heading the *Students' Journal and Hospital Gazette* of Saturday last makes the following remarks:—

"The Queen's University in Ireland is receiving considerable castigation from some members of the Medical Press. The MEDICAL PRESS AND CIRCULAR has had some severe strictures recently on its educational deficiencies. It would appear from the remarks of our contemporaries that the standard of general education in the Queen's University is a very low one, and not such as to tend to raise the status of its medical graduates. Into this question, however, we will not here enter, but leave our contemporaries to deal with it. It would appear, however, that the Queen's University authorities and some of its *alumni*, smarting under the criticism of the MEDICAL PRESS AND CIRCULAR, have adopted a very petty mode of avenging themselves. This they have done by transferring their advertisements and subscriptions to other journals. Remarking on this, our contemporary the M. P. & C. says: 'We feel complimented by this display of irritation on the part of the University, because it makes us aware that our strictures upon its educational management hit the mark and produced an effect upon the medical public. We would feel greater regret for the necessity which obliged us to speak upon the subject if we saw that the representatives of the University had sense and temper to hear the truth about themselves.'"

Obituary.

DR. WARBURTON BEGBIE.

WE regret to have to announce the death of Dr. Begbie, M.D., F.R.C.P., of Edinburgh, which took place on Friday last. The event was not unexpected, as his condition for some time has been the source of very grave anxiety to his friends. Dr. Begbie was formerly Physician to the Royal Infirmary, to the Royal Hospital for Sick Children, Examiner in Medicine at the Royal College of Physicians, and also in the University of Edinburgh.

We shall next week give a notice of the life of this eminent physician.

Correspondence.

CHARITY ELECTIONEERING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 31st of October, 1873, the memorable meeting on Charity Electioneering was held at the Mansion House, the whole of the London Press, with the solitary exception of one weekly paper, supporting the reform party. On that occasion the reforms which have been ever since consistently advocated by the Charity Voting Reform Association, were clearly put forward as being the alterations essential in cases where it is still desired to continue the system of voting by the whole body of subscribers. These requisite alterations are few and simple, namely—

MODE OF VOTING.

1. That it be made essential to the validity of a vote that the initials of a voter be placed against the name voted for; that the signature be appended in full, with address and date, and that the voting paper be returned by the subscriber direct to the secretary of the charity.

CANVASSING.

2. That all canvassing by circular, and all personal canvassing by the candidates or representatives be prohibited under pain of exclusion from all prospect of benefit or forfeiture of all benefits, if already elected.

POLLING DAY, ETC.

3. That the system of polling days, leading to traffic in votes, be discontinued. Subscriptions paid within a short period of the day of election not to confer the power of voting till the following election.

COMPARATIVE SELECTION.

4. That the list of condidates be not excessive in proportion to vacancies, and that admission be the result of comparative selection.

It is a great satisfaction to us to report that the Press has proved itself not only a sound guide for public opinion, but also its true exponent. For the result of that great defeat at the Mansion House, amidst noise and violence, has been up to the present time—

1st. The formation of the Charity Voting Reform Association, now counting 4,200 members, amongst whom may be found some of the most distinguished and liberal philanthropists in our land.

2ndly. The adhesion and support of 500 subscribers of the British Orphan Asylum.

3rdly. The same on the part of 1,927 subscribers of the Governess Benevolent Institution.

4thly. The same in the case of 2,098 subscribers of the Royal Medical Benevolent.

5thly. The same in regard to 675 subscribers to the Friend of the Clergy Corporation.

(These three last having memorialised their managing committees in favour of reform.)

6th. The very satisfactory result of the public meeting of the National Orphan Home at the London Tavern on the 24th of last month. On that occasion the following resolutions were proposed and carried by a decided majority of those present, and also of those who sent proxies:—

1st. That the public election of candidates from and after the present election be abolished, and that in future all votes duly filled in and signed be sent under seal addressed to the scrutineers at the office not later than the day before that fixed for the election.

2nd. That all canvassing, personally, by circular, or card, on the part of the candidates or their relatives be in future prohibited, on pain of forfeiture of all benefits of the institution, and that no addresses be inserted in the list of subscribers unless they desire the same.

3rd. That money paid on the day of election shall not secure votes at such election.

4th. That the committee shall regulate the number of candidates in accordance with the vacancies existing and the number to be elected.

On these resolutions being put and carried, several of the poor widows (allowed to be present after the polling) came forward and expressed their thankfulness for the blessing just conferred, by which they and their fellows would be released by this most happy indulgence from the heart-wearing penance to which they had hitherto been doomed. It may be added that several other institutions have taken steps towards reform in the direction you have indicated, and it is hoped that before long your suggestions and our labours may be crowned with that entire success which not only Christian charity but common humanity demands.

I am, Sir,
Your obedient servant,
R. J. SIMPSON,
Rector of St. Clement Danes, Hon. Secretary Charity Voting Reform Association.

30 Charing Cross, London,
5th February, 1876.

VIVISECTION.—UNNECESSARY CRUELTY IN MEDICAL TEACHING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I wish to ask, you is it necessary, or of benefit to the education and morality of students of medical jurisprudence, that the experiments, most, if not all of which are described in their text-books, viz., the action of poisons, &c., on dogs and other animals, should be made, as I am informed they are in one of the Queen's Colleges? And, if it is necessary, whether it ought not to be done with as little torture to the poor animals as possible.

One dog was so tortured the other day as to completely disgust a number of the class. The professsor attemped to show the effects of phosphorus on the animal's economy, and, and stuffed a lot of it into the poor dog's mouth, and wilfully or carelessly allowed him to chew it, when, horrible to relate, it took fire, and the agonies the wretched animal endured were awful to witness.

May I hope that you will publish this and also bring your influence to bear on this inhuman proceeding, and so induce the authorities to interfere.

Yours truly,
A POOR DOG.

Medical News.

Royal College of Physicians of London.—On Tuesday, February 22nd, the following gentlemen were admitted Licentiates of the College.

Frederic William Baily, St. Leonard's.
Albert De Winter Baker, 27 Trinity Street, S.E.
William Gilbert Dickinson, 2 Belle Vue, N.W.
William Edward Norton Erith, 31 Yonge Park, N.
Sidney Westbrook Iorwerth Joseph, St. Leonard's.
Alexander Gairdner Lacy, Guy's Hospital, S.E.
Henry Howard Murphy, 8 Westgate Terrace, S.W.
Walter Roughton, 42 Hammersmith Grove, W.
Arthur Huelin Wilson, St. George's Hospital, S.W.

The following candidates, having passed in Medicine and Midwifery, will receive the College Licence on obtaining a Qualification in Surgery recognised by this College:—

Joshua Sidney Pearce, University Hospital, W.C.
Herbert Sloman, Farnham.

Indian Medical Service—List of Candidates who were successful at the competitive examination held at Burlington House on 14th February 1876:—

1 Tomes, A.	13 Henderson, W. G. H.
2 Maitland, J.	14 Boyd, H. W. B.
3 Peevor, G. H.	15 Swaine, C. L.
4 Stewart, A. K.	16 Hamilton, H.
5 Dantra, S. H.	17 Cobb, R.
6 Mawson, W. A.	18 Dalal, K. A.
7 Meredith, E. B.	19 Stephens, A. E. R.
8 Macdonald, D. I.	20 Smith, M. H.
9 Walker, G. L.	21 Farrell, P. I.
10 Macgrigor, J.	22 Hunter, J.
11 Doyle, B.	23 Halpin, N. G.
12 Cadge, W. H.	

Twenty other candidates passed at the same examination, who will be required to wait until the necessary vacancies occur.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,856 births and 4,871 deaths were registered in London, and twenty-two other large towns of the

United Kingdom. The mortality from all causes was at the average rate of 32 deaths annually in every 1000 persons living. The annual death-rate was 28 per 1000 in Edinburgh, 30 in London, 35 in Glasgow, and 45 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 19, Hull 20, Leicester 22, Sunderland 22, Portsmouth 25, Newcastle-upon-Tyne 27, Birmingham 28, Brighton 29, Leeds 29, Wolverhampton 29, Bradford 29, Sheffield 30, Plymouth 32, Bristol 33, Oldham 37, Manchester 39, Salford 40, Nottingham 42, and Liverpool 42. The annual death-rate from the seven principal zymotic diseases averaged 4·4 per 1000 in these towns, and ranged from 0·0 and 1·0 in Norwich and Brighton, to 9·5 and 11·3 in Liverpool and Salford. The fatal cases of scarlet fever in Bristol showed a further increase upon those in recent weeks. Seven more deaths were referred to fever in Sheffield, and 10 to small-pox in Manchester and Salford; five fatal cases of small-pox also occurred in Liverpool. In London the 2,005 deaths included 40 from scarlet fever, 17 from different forms of fever, 13 from diarrhœa, and not one from small-pox; the seven principal diseases of the zymotic class causing 256 deaths against 242 and 222 in the two preceding weeks. These 256 deaths were 17 above the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 3·8 per 1000. There were 130 deaths from whooping-cough, showing an increase of 30 upon those in the previous week, and exceeding by 61 the corrected average number in the corresponding week of the last ten years. The deaths referred to diseases of the respiratory organs, which in the two previous weeks had been equal to 473 and 465, rose last week to 622, which exceeded the average weekly number in the coresponding week of the last ten years by 241; 410 resulted from bronchitis and 118 from pneumonia.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. Cogswell.—Letter on "Hastings Water Supply" received.

Medical Society of the College of Physicians, Ireland.—A special meeting will be held this (Wednesday) evening, at 8½ p.m., for the consideration of the new rules of the Society, as revised by the Council and approved of by the College.

The British and Indian Medical Departments.—We have received the following comparison of the two services from a correspondent who does not give his name, and does not state the origin of the extract. As it seems to state the case fairly, we give it *quantum valeat:*

"I am glad you have asked my advice as to whether you should, at the approaching examination, compete for the British or Indian Medical Department—for in the conditions of these services there are some points not generally well known.

"1st—In either service you may expect about the same number of years in India and the same number of years at home; but in the Indian Department your years at home will be on leave, in the British Department on duty.

"2nd—Whether serving in India or at home on furlough, the pay of the Indian Department is much higher.

"3rd—Promotion after twelve years is the rule in the Indian Department; after fifteen years in the British Department.

"4th—The regulations for sick leave are so much more liberal in the Indian Department, that there is much less chance of your having to resign from ill health than in the British Department.

"5th—The regimental system having been abolished, both services are now departmental, but the appointments in the Indian service are much more permanent than in the British."

The Hastings Water Supply.—We have received three letters on this subject, upon which we have recently commented. Mr. Cogswell's is too long for our present issue, and the other two correspondents write thanking us "for the valuable help we have rendered the town," at the same time stating "there are signs both in the Town Council and the local press, of a real desire to improve matters, and to place Hastings in the eyes of the profession and the public as its natural beauties warrant, and as one of the leading, most healthy, and best of our English watering places."

Communications, Enclosures, &c., have been received from—Mr. Pye Chavasse, Birmingham. Dr. Waters, Chester. Dr. Octavius Sturges, London. Mr. Alfred Smee, London. Dr. Day, Geelong. Dr. Arthur Downes, Hastings. Dr. Harvey Hilliard, Holloway. The Registrar of the College of Physicians of London. Dr. De Berdt Hovell, Clapton. Dr. Thornley, Leicester County Lunatic Asylum. Dr. Cockcroft, Hurworth. Mr. Bailey Walker, Manchester. Dr. Palfrey, London. Mr. Williams, Lincoln. Dr. Langley, London. Dr. Bramwell, University of Durham. Mr. W. T. Law, Hampton Court Palace. The Secretary of the Indian Medical Department. Mr. W. H. Preece, London. The Registrar of the Medical Council. Dr. Leared, London. Rev. J. Alton Hatchard, St. Leonards-on-Sea. Mr. Caulfield, Hastings. Rev. H. B. Wilder, Sulham, Reading. Capt. Fortescue, Bloomsbury. Dr. Ashburton Thompson, London. Dr. Gordon, India. Mr. Ifield, London. Dr. Robert McDonnell, Dublin, Mr. Swan, Dublin. Dr. Coombs, Castle-Carey. Mr. Cogswell, Hastings. Mr. Atcherley, Holloway. Dr. McDermot, Ballyfeared. Dr. Nicolls, Ballinalee. Dr. Wright, Netley. Dr. Fisher, H.M.S. *Iron Duke.* Dr. Skinkwin Cork. Dr. McCabe, Dundrum. Dr. Browne, Rathmines. Dr. O'Reilly Moville. Dr. Carleton, Delvin. Dr. Furlong, Streamville. Dr. Russell Thurles, &c., &c.

VACANCIES.

Lincoln Lunatic Hospital.—Resident Medical Superintendent. Salary £150, with board and residence. (See Advt.)

University of Durham College of Medicine.—A joint Lecturer on Anatomy and a Medical Tutor. Salary of the latter, £200. Full information of Dr. Bramwell.

Nottingham Dispensary.—Assistant Resident Surgeon. Salary, £170. Applications, with testimonials, to the Committee at the Dispensary.

Lisnaskea Union.—Medical Officer Brookeborough Dispensary District. Salary, £115, with £15 extra as Sanitary Officer. (See Advt.)

University of Glasgow.—Examiners in Medicine. Applications to be lodged with Mr. Kirkwood, 166 West George Street, Glasgow.

Kent County Lunatic Asylum.—First Assistant Medical Officer. Salary, £220, with furnished apartments, &c. Address the Clerk to the Visitors, Maidstone.

Birmingham General Hospital.—Resident Surgical Officer. Salary, £130, with board. Applications to the House Governor.

Manchester Royal Infirmary.—Hon. Assistant Surgeon. Particulars of election of the Secretary.

Camberwell Workhouse Infirmary, Surrey.—Medical Officer. Salary, £250, with house. Full particulars of the Clerk, Peckham Road, Camberwell, S.E.

Somerset County Lunatic Asylum.—Assistant Medical Officer. Salary commencing at £100, with board, &c. Apply to the Medical Superintendent.

APPOINTMENTS.

Banham, Dr. H. F., Physician to the Sheffield General Infirmary.

Barker, J. E., M.B., Medical Attendant to the Royal Irish Constabulary, Kilcullen.

Bloxam, J. A., F.R.C.S.E., Surgeon to the Out-patients at the Lock Hospital, London.

Critchett, G., F.R.C.S.E., Ophthalmic Surgeon to the Middlesex Hospital.

Griffith, G., M.R.C.P.Ed., Medical Officer of Health for the new Milford Port Sanitary District.

Herman, G. E., M.R.C.P.L., Assistant Obstetric Physician to the London Hospital.

Hill, B., M.B., F.R.C.S.E., Surgeon to the Lock Hospital, London.

Jones, A. H., M.R.C.S.E., House Surgeon to Guy's Hospital.

MacSweeney, J. P., L.K.Q.C.P.I., Medical Officer, &c., for the Ballycroy Division of the Achill Dispensary District of the Newport Union, co. Mayo.

Matupin, L., L.R.C.S.I., Medical Officer, &c., for the Achill Division of the Achill Dispensary District of the Newport Union, co. Mayo.

Miller, G., M.D., F.F.P. & S. Glas., Out-door Physician for the Western District of the Glasgow Lying-in Hospital.

Morgan, E. A., L.K.Q.C.P.I., M.R.C.S.E., a Dental Surgeon to the Liverpool Dental Hospital.

Newby, D., M.D., M.R.C.S.E., Public Analyst for Great Grimsby.

Page, H. W., M.B., F.R.C.S.E., Assistant Surgeon to St. Mary's Hospital.

Plant, H. W., M.B., C.M., a Resident Surgeon to the Birmingham General Dispensary.

Royle, A., M.R.C.S., Surgeon in Ordinary to H.R.H. the Prince Leopold.

Saunders, J. C., M.A., Lecturer on Botany at the Charing Cross Hospital Medical School.

Shera, H. A., L.R.C.P.Ed., L.M., M.R.C.S.E., House Surgeon to the Sheffield Public Hospital and Dispensary.

Smith, S. Ll., L.R.C.P.Ed., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 8 District of the Parish of St. Pancras, London.

Wallace, Dr. R. S., Out-door Physician for the Central District of the Glasgow Lying-in Hospital.

Births.

Blakely.—On the 26th ult., at Fivemiletown, co. Tyrone, the wife of S. Blakely, M.D., of a son.

Winslow.—On the 26th ult., at Hammersmith, the wife of Dr. Lyttleton Forbes Winslow, of a son.

Deaths.

Begbie.—On the 25th Feb., at his residence in Edinburgh, J. Warburton Begbie, M.D., F.R.C.P., aged 52.

Day.—On the 14th Feb., at Portland Square, Bristol, Frederick A. E. Day, M.R.C.S.E., aged 41.

Duke.—On the 11th Feb., at Cadogan Terrace, South Hackney, B. Duke, M.R.C.S.E., aged 27.

Hardie.—On the 11th Feb., at Alva Street, Edinburgh, Joseph R. Hardie, M.B., aged 30.

Humfrey.—On the 8th Feb., at Malta, Alex. Humfrey, L.R.C.S.I., Surgeon-Major 98th Regt.

Hunt.—On the 14th Feb., at Silverstone, Wm. J. Hunt, L.R.C.P.L., aged 38.

Lucas.—On the 21st Feb., at Burlington Street, Liverpool, Jas. Lucas, M.R.C.S.E.

Massy.—On the 10th Feb., at Monkton-Combe, Somersetshire, Hugh N. Massy, Surgeon, aged 77.

Nason.—On the 23rd Feb., at 21 Cambridge Terrace, Kingstown, John W. W. Nason, M.D., eldest son of the Rev. W. H. Nason, of Rathcormack and Newtown, co. Cork.

IRISH POOR-LAW INTELLIGENCE.

CERTIFYING OF LUNATICS IN IRELAND.

THE case put to us a few weeks since as to whether the dispensary medical officer had the exclusive right to receive a fee for certifying dangerous lunatics under the Act of 1875, and decided by us in the affirmative, has been submitted by Dr. M'Craith, of Mitchelstown, to Mr. Gerald Fitzgibbon, Q.C., whose opinion we record below, giving the queries asked and counsel's reply to each.

ADVICE AND OPINION OF GERALD FITZGIBBON, ESQ., Q.C.

The statutes governing this case appear in my opinion to be reasonably clear under 30 and 31 Vic., cap. 118, sec, 10 : it is not lawful to commit any dangerous lunatic except upon the medical certificate thereby required—namely, a certificate (1) of the medical officer of the dispensary district in which the committing justices shall be at the time when the lunatic is brought before them. (2) If there be more than one such medical officer, *then*, and then only, of the nearest available medical officer of such district. Or, (3) If there be no such medical officer available, then, and then only, of the nearest available medical officer of any neighbouring dispensary district. The law is clear that no one except a medical offieer of a dispensary district can under this section lawfully give a certificate, and it is equally clear that the 14th section of 38 and 39 Vict., cap. 67, did not make any other alteration in the law than to allow the committing justices to order a payment to any such medical officer, not exceeding two pounds, for his remuneration and expenses in reference to the examination. Therefore Dr. O'Neill's payment cannot be legally defended unless he be such a medical officer as is mentioned in the first statute. The dispensary district medical officers are appointed under the Medical Charities Act, 1851, sec. 8 ; whereas, so far as I can ascertain, the workhouse medical officers are appointed under the Relief Act, 1838, are union officers, and are not empowered to grant any certificate under the Lunacy Acts.

Counsel is requested to advise whether Querist or Dr. Reardon has any and what remedy to recover the £2 paid Dr. O'Neill, and from whom, and how ?

It is very doubtful, however, that the £2 paid to Dr. O'Neill could be recovered back from him, though I think it could. On proof that the money was received for a service which could not be lawfully performed except by Dr. M'Craith, and obtained by forms and orders applicable only to him, I think the £2 might be recovered by Dr. M'Craith on a civil bill process as money received to his use by Dr. O'Neill, but a claim should be added seeking it as damages for interference with him in the performance of the duties of his office. However, this remedy is not certain, and it would not be likely to have as general an effect as a proceeding to quash the orders or disallow the credit, and if Dr. M'Craith can obtain the support of his professional brethren, he ought to proceed in the more formal way to get a decision upon the principle ; but the expense would be large, and an individual should not incur it without consideration.

Have Querist or Dr. Reardon any and what rights to proceed in the Queen's Bench, or other Court, by application for mandamus or certiorari, or in any other manner ? and if so, will Querist or Dr. Reardon get their costs of such proceedings against any and what persons ? and if so, Counsel is requested to direct fully the course to be pursued, and to draft any affidavits if necessary.

Is the detention and support of Margaret Hannon in the Cork District Lunntic Asylum under the circumstances illegal ? and are any and what persons liable to an action at suit of said Margaret Hannon or other person for such detention ? and is it not illegal to charge the cost of the support of said Margaret Hannon on the funds of said Cork District Lunatic Asylum ? and is not Querist, as a ratepayer under the Poor-laws for Mitchelstown, which contributes to the funds of said Cork Asylum, entitled to require the Board of said Asylum not to charge said Margaret Hannon's support on the funds of said Asylum, but against some other and what persons ? And should said Board not comply with such request of Querist, has not Querist a remedy, and what is it, whereby to compel said Board not to charge said fund with her support ?

Said Margaret Hannon having been committed from Querist's Dispensary District without Querist's certificate, is not Querist entitled to require said Board or other person to have said Margaret Hannon certified by Querist, and to pay Querist's fee therefor ?

The Mitchelstown Board of Guardians having paid Dr. O'Neill said fee of £2, is not Querist entitled to object to same being allowed by Auditor, when auditing said Board of Guardians' next accounts, and if allowed then by the Auditor, cannot Querist successfully dispute same in the Queen's Bench or other Court ? and who will have to bear the expense of such proceedings ? Also, cannot Querist, as such ratepayer, successfully make a similar objection before the Auditor, when auditing the Cork District Lunatic Asylum accounts, as to the support of said Margaret Hannon being charged on the Asylum's funds ? and, if same be overruled, cannot Querist likewise successfully dispute same in the Queen's Bench, and with whom ?

If the warrants of committal have been filled up by the magistrates describing Dr. O'Neill as the nearest available dispensary district medical officer, and are good on the face of them, I do not think the committals void until quashed, and the detention and support of the lunatics under them would not be illegal. If the warrants do not show on the face of them that Dr. O'Neill was qualified to certify, then I think the officers of the asylum were not justified in receiving the lunatics, and the detentions are illegal, and the discharge of the lunatics might be formally ordered on Habeas

Corpus, but new and correct warrants could be immediately obtained, and any proceeding taken to make any one responsible in damages or otherwise for the detention of persons who are, I presume, proper subjects of restraint, would, if instigated by a medical officer to enforce payment of his fees, be justly censured. The same observation, but less strongly, applies to any proceeding to surcharge the maintenance of the lunatics in question.

Querist cannot now require Margaret Hannon to be certified by him, nor can he maintain any proceeding for his fee against any other person than Dr. O'Neill, as to whose liability I have advised above. The justices cannot be in any wise *compelled* to order payment of the fee, and the dispensary officers cannot refuse to examine lunatics when required by the justices to do so; therefore, as a matter of prudence, any hostile proceedings should be avoided if possible.

Querist is in my opinion clearly as a ratepayer entitled to dispute the allowance by the auditor of any fee paid to any other person than himself for the examination of dangerous lunatics within his district, and if the auditor allows the credit, I think the order of the justices for the payment could be successfully assailed and quashed in the Queen's Bench on certiorari. The expense of the proceedings would be in the discretion of the Court, who might, if there had been wilful misconduct on the part of the justices, order them to pay the costs, but in all probability no costs would be given on either side. A similar application may be made in the case of the Asylum, but its result will depend, as I have mentioned, on the formal sufficiency of the committal. I advise Querist—1st. To object to the credit for the £2 in the guardians' accounts, and if it be allowed by the auditor, to proceed in the Queen's Bench. 2nd. To object to the credits in the Asylum accounts, and to insist, if the warrants do not show the certifying officer to be qualified, that the officers of the Asylum shall be disallowed the credits, thus showing them that it is their duty to see that the warrants show the proper officers to have certified before they receive the patients. In this instance, also, if the credits be allowed, a proceeding to surcharge them may be taken, but its form would depend on the terms of the warrant in each case, and on whether it described on the face of it the rectifying medical officer or an authorised officer.

It is unnecessary to observe that Dr. M'Craith is animated by no spirit of hostility whatever with regard to Dr. O'Neill, the workhouse medical officer, but desired simply to establish in legal form, either by a process in the inferior or a mandamus in the superior courts, or in such way as he might be advised, the legal right of the dispensary medical officers to the emoluments of certifying in lunacy. If the Local Government Board had taken the responsibility of declaring *ex cathedra* the state of the law on the subject, Dr. M'Craith's purpose would have been served. It was strictly their function to do so, inasmuch as the Guardians were called upon to pay an illegal charge; and it was the duty of the Local Government Board auditor to see that no such charge was paid. The Commissioners decided to shirk the responsibility, as they have done in other questions of law interpretation, in which it was plainly their duty to express an opinion; and we entirely concur in the regret expressed by the learned counsel that they should pursue this policy of reticence. In bringing his opinion to a termination, Mr. Fitzgibbon says:

Before taking either of these proceedings, I would advise Mr. M'Craith to send forward a memorial to the Chief Secretary, and another to the Local Government Board, stating what has occurred, and praying that directions to observe the law in future may be given to the justices. I cannot concur in the view of the Local Government Board expressed in the letter of 22nd December, 1875, that "the question whether the magistrates have acted correctly in making an order in favour of Dr. O'Neill is not one for the Local Government Board to decide, but the guardians being served with the order would be justified in paying it." It seems to me, with all due respect to the Board, that the Act of Parliament very distinctly provides that the only orders which the guardians can lawfully pay are orders made in favour of dispensary district medical officers, and any other orders are illegal, do not justify any payment, and afford no protection against surcharge. Having regard to the public inconvenience which would arise if I be right in this view, and to the danger that the legal authority to detain lunatics may be affected by the neglect to obtain the proper certificate, I would suggest that Mr. M'Craith should call the attention of the Local Government Board in any memorial that he may forward to these considerations, and it possibly might be useful to annex a copy of this opinion.

GERALD FITZGIBBON, Q.C.

10 Merrion Square North.

As the result of this correspondence, the following letters have been addressed to Dr. M'Craith:—

Dublin Castle, 26th January, 1876.

SIR,—I am directed by the Lord-Lieutenant to inform you that his Grace has caused inquiry to be made as to the warrant under which Mary Anne Hannon was committed as a dangerous lunatic to the District Lunatic Asylum at Cork, referred to in your letters of the 16th and 30th ult., and he is advised that the committal having taken place in the Mitchelstown Dispensary District, of which you are the medical officer, you, and not Dr. O'Neill, should have been called in by the magistrates.

I am to add that a communication has been made to the magistrates on the subject for their future guidance.

The enclosures of your letter are herewith returned.

I am, Sir, your obedient servant,

T. H. BURKE.

Edward M'Craith, Esq., M.D.,
Mitchelstown.

Local Government Board, Dublin,
18th February, 1876.

SIR,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 29th ult., enclosing copy of a communication which you have received from the Under-Secretary to his Grace the Lord Lieutenant relative to the warrant of the magistrates, upon which a woman named Margaret Hannon was recently committed as a dangerous lunatic to the District Lunatic Asylum at Cork; and also forwarding copy of an opinion which you have obtained from Mr. Gerald Fitzgibbon, Q.C., on the question of legality of the warrant of committal, and of the order made on the Board of Guardians of the Mitchelstown Union for payment of the fee provided by the 14th Section of the Lunatic Asylums (Ireland) Act, to Dr. O'Neill, who is not the medical officer of the dispensary district in which the committing justices were at the time the lunatic was brought before them.

The Local Government Board have brought the case under the consideration of the gentleman who audits the accounts of the Union, and also the accounts of the Lunatic Asylum. But as the magistrates have received directions from Chief Secretary's office, they are not likely in future to adopt a course similar to that pursued by them in the present instance.

By order of the Board,

B. BANKS, Secretary.

CERTIFYING DANGEROUS LUNATICS.

TO THE EDITOR.

SIR,—I perceive there is a paragraph on this subject in the last MEDICAL PRESS AND CIRCULAR, in which my case is mentioned, and the editor makes the following remark :—"He cannot see why they (the workhouse medical officers) should be disentitled to certify a dangerous lunatic." My answer to that is simply the following :—Why should the Legislature consider that a dispensary medical officer is not qualified or considered worthy to receive a fee for examining and certifying a dangerous lunatic until very lately? Has not such been the law for years past? Is not the labourer worthy of his hire? Would a workhouse medical officer attend were he informed he would get no fee? *Dare* a dispensary medical officer refuse to attend, examine, and certify even at present without fee or reward? The act, you know, is compulsory. Why should the workhouse medical officers come in now and reap the benefit of the gratuitous services performed by the dispensary officers during many years past? Does it stand to reason, or would it be in accordance with law or equity? Why did not the Act order them, as it did the dispensary medical officers, to examine and certify without fee or reward?

If a mistake has been made, I hold that it was in compelling the dispensary officers to render gratuitous services to the public. I ran a very great risk on one occasion in going to visit a dangerous lunatic, and for which I was to receive neither fee nor reward. The lunatic on seeing me approaching fastened the door, refused to admit me, and deliberately cut his throat. I believe his first intention was to cut my throat or run me through with a pitchfork, I being alone, and the Legislature until very recently considered such services were undeserving of fee or reward. And now other claimants are to reap the benefit. Why not share the danger? As you have published a portion of my first letter, which called forth the editorial remark, I hope and expect you will publish this my answer thereto, and I remain,

Yours very sincerely,
E. M'CRAITH.

[It is true that dispensary medical officers were most unjustly saddled with the gratuitous discharge of a very unpleasant duty. Also true that they are now legally entitled to a monopoly of the emoluments from certifying dangerous lunatics. Not proven, however, that these circstances give them a claim morally superior to that of the workhouse medical officer. If it becomes necessary for the Legislature to select a local medical officer for a certain duty, it is perhaps reasonable that the dispensary surgeon shall be selected, he being the officer of a district, and therefore more easily to be found than the workhouse medical officer, who is the official of a union which may be situated at a distance. In all other respects the equal rights of workhouse medical officers ought, in our opinion, to be recognised.—ED. M. P. & C.]

CARLOW UNION.

BAGENALSTOWN DISPENSARY AND FEVER HOSPITAL.

A LETTER was read from the Local Government Board, enclosing copy of a communication forwarded by them to the Bagenalstown Dispensary Committee relative to explanation given by Dr. Scott as to reply to certain queries submitted to them on his election by the Committee as Dispensary Medical Officer of the district. In their reply the Local Government Board declined to sanction the appointment, observing that it would appear Dr. Scott was one year older than Dr. Trayer, who had retired from the appointment.

A second letter was read from the Local Government Board relative to superannuation allowance granted to Dr. Trayer on his resigning the appointment of Dispensary Medicrl Officer, owiug to ill health. The Board in their letter observed that Dr. Trayer hitherto held the appointment of medical officer of the Bagenalstown Fever Hospital, and they wished to be informed if he intended to resign that appointment.

BALLINA UNION.

EXAMINATION OF ANOTHER LUNATIC.

AN order under the hands and seals of Mr. Mitchell and Mr. Geo. Orme, two justices, directing the payment of £1 1s. to Dr. Scott, for examining Thomas William Lougheed, a supposed lunatic, was laid before the board.

The Chairman suggested that the opinion of the Local Government Board be obtained as to whether the justices could order payment of a doctor's fee where the lunatic was not destitute ; whatever the letter of the law might be, in spirit it could scarcely be that the examination of lunatics who were not destitute was directed, the doctor's fee being paid out of the rates.

Dr. Scott—I attended this person on a red ticket.

Mr. Crean—That proves nothing. *Dr. Thompson here has attended a member of the dispensary committee on a red ticket.*

Mr. Little—It shows there must be something wrong in the law when this can be done.

Mr. Crean—No doubt of it.

Chairman—We think a great deal of giving 2s. a week to a poor person as out-door relief, but here every other week an order is made upon us to pay doctors' fees, no matter what the circumstances of the party.

Clerk—That is the law.

Chiarman—It is strange if the law provides for the payment of a doctor where the person examined can himself pay, as this patient.

Mr. Thompson—Your question cannot apply to this case, for if the boy applied for admission to the house you could not refuse him. His father could not be compelled to support him.

Chairman—It can do no harm to ask the question.

Mr. Crean thought the magistrates should inquire into the means of lunatics before making an order for payment on the board of guardians.

The following minute was approved of :—

"Approved for payment in this case, but the guardians request the Local Government Board will inform them if the guardians are bound to pay a fee to a doctor for examining a lunatic whose parents are not destitute."

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week was 41, including 5 from fever (4 typhoid and 1 simple continued fever), 13 from whooping-cough, 7 from scarlet fever—5 of which occurred in No. 1 North City (Summer-hill) District, 4 from croup, 2 each from erysipelas, influenza, and diarrhœa, 1 from measles, &c. Sixteen children died from convulsions.

Bronchitis caused 73 deaths (against an average of 38 for the correspouding week of the previous ten years), pneumonia 9, pleurisy 1, asthma 1, and lung disease unspecified 7.

Six deaths were attributed to paralysis, 1 each to apoplexy and epilepsy, and 3 to brain disease unspecified.

Eight deaths resulted from heart disease, 3 each from liver disease and Bright's disease, and 1 from kidney disease unspecified.

Phthisis caused 32 deaths (being 10 over the average for the seventh week of the ten years 1866-75), hydrocephalus 4, mesenteric disease 2, scrofula 1, and cancer 3.

Six accidental deaths were registered, viz., 3 from burns 1 from scalds, and 2 from fractures and contusions.

Two deaths from fever, 2 from whooping-cough, and 1 each from scarlet fever and diarrhœa were registered in Belfast.

Four deaths from measles and 1 from whooping-cough were registered in Cork.

Five deaths from whooping-cough and 1 from diarrhœa were registered in Limerick.

REPORT OF THE INSPECTORS ON THE LUNATIC ASYLUMS IN IRELAND.

(Continued.)

The expediency of instituting some countervailing influence against the undue repletion of asylums from poorhouses can probably be best upheld by a power of removal with the sanction of the Inspectors, and on definite certificates to the safety thereof from visiting and medical physicians to these establishments is so clear as to require little comment. For our own part we are satisfied that the permanent utility of the lunatic department will be best consulted by confining expenditure within reasonable limits, at the same time not omitting to watch over the comfort and requirements of all denominations.

Without entering into the relationship of cause and effect as regards our inspections, it may be safely said, that from year to year a progressive amelioration has been noticeable in the condition of the mentaliy affected in the poorhouses of Ireland who, as a rule, have come to be recognised in a proper light, and made objects of kindly consideration by Boards of Guardians. They are afforded a special dietary, with animal food from three to six days in the week. Their clothing and bedding are improved, and personal cleanliness more carefully looked after. When the number of insane is large, separate apartments with a paid attendant for each sex is usually provided, or well disposed paupers, encouraged by some additional domestic allowances, are employed, and when grounds or open airing yards are available full opportunity for exercise is afforded. In a few workhouses we have found many of the imbecile and idiotic industriously employed in day-ro oms set apart for them and, we not unfrequently learn from both masters and matrons that some of them are the most useful and willing of the inmates.

(To be continued.)

FOR AND AGAINST ANIMAL VACCINATION. (a)

By Charles R. Drysdale, M.D., M.R.C.P. Lond., F.R.C.S. Eng.,

Senior Physician to the Metropolitan Free Hospital; Physician to the North London Consumption Hospital; and Consulting Physician to the Farringdon General Dispensary.

(Continued from p. 87.)

It is, again, objected to animal vaccine that it cannot be kept in tubes, in this being inferior to human lymph. It is alleged against the practice of animal vaccination by Bousquet, of Paris, and Crocq, of Brussels, that by making use of it to vaccinate children at the various institutes it diminishes the supply of humanised vaccine in many quarters, that it turns away the public from arm to arm vaccination, and concentrates the vaccine in a few hands as a species of monopoly. Crocq criticises with much force the opinion emitted by the Academy of Medicine of Brussels in 1857, that "Human vaccine lymph gradually becomes weakened by successive transmissions, without, however, on that account losing its preservative property. It is, then, useful, and even necessary, to renew the vaccine virus whenever it is possible to procure cow-pox." If this were true, says Crocq, small-pox, syphilis, and other viruses would tend to become extinct in course of time, which, alas! is only too untrue. The acarus scabiei and the trychophyton never change their virulence: it is the soil that makes viruses flourish or decay. The vaccine vesicle of our day is as well-marked as it was in the days of Edward Jenner, and as it is figured in his work on Variolæ Vaccinæ. Warlomont alleges that one cause of the degeneration of vaccine lymph is the use of lymph from revaccinations. Nine times out of ten, he alleges, vaccination fails when made with this lymph. In armies, when it is thought right to revaccinate the men suddenly, it is often the practice to procure vaccine lymph from an infant, and with it to vaccinate some adult whose arm has only slight traces of a first vaccination, and make such persons the vaccinifers of the whole troop. In such a case animal vaccine, he points out, would be far preferable.

Marson and others say that if revaccination be carefully performed, it completely shelters those on whom it is practised. The well-known example of the servants of the London Small-pox Hospital is given, where, for thirty years, not a single servant contracted the disease, one of the rules being that they should be revaccinated before admission. Dr. Balfour ("Med. Chir. Transactions," 1862) mentioned that the number of cases of small-pox in the British army had not been more than 6·6 per 10,000 men for a long series of years, one-fifth of these men being protected by previous small-pox, and four-fifths by revaccination. Animal vaccination could not have done more than that. Seaton also expresses his opinion that he has never seen anything to warrant the notion that the general supply of lymph of this country had undergone any necessary deterioration. He finds the vaccinators of the present day, who are masters of their craft, doing their work with ordinary long-humanised lymph, and infecting their patients as completely as the earlier vaccinators did (Reynolds' "System of Medicine," 1866, p. 505). In Germany the same arguments are used. Thus Heim found that in five years there had occurred among 14,384 revaccinated soldiers in Würtemberg only one instance of modified small-pox.

Marson, West, Paget, and others are cited by Seaton (*Pa. C. J.*, p. 509) as saying *they* have never witnessed any case of vaccino-syphilitic contagion. Seaton, in 1866, too, was a disbeliever in vaccino-syphilitic contagion.

In attempting to come to a provisional conclusion after hearing what has to be said for and against animal vac-

(a) Read at the Medical Society of London on the 15th November, 1875. Dr. Routh, President, in the chair.

cination, perhaps I may be permitted to state that it seems at present to me—

1st. That the addition of animal vaccination to the duties of our State Vaccine Department in Whitehall might be advisable for the following reason: In times when small-pox is epidemic, as it has so frequently been of late years (and in Paris in 1870 as many as 3000 persons in one day presented themselves for revaccination at the vaccine department of the Academy of Medicine), it would be possible, by employing animal vaccination, to obtain in a few days an unlimited amount of admirable vaccine matter, capable of being at once transmitted on points to all practitioners in infected districts. Dr. C. Paul used to inoculate two calves daily in the epidemic of Paris in 1870.

2nd. I think there can be no doubt in the minds of instructed and unprejudiced medical men that syphilis has occasionally been rather widely propagated by means of vaccination. In all countries, then, where vaccination is rendered obligatory, it would seem but fair to give to very scrupulous persons the choice, whether they would allow their children to be vaccinated from another infant, or from the calf. Doubtless, most of us would continue to make use of the Jennerian lymph, seeing that syphilis is so very rarely conveyed by it; but we need no longer force any other practitioner or layman to do so against his will.

3rd. Although I am convinced that Jennerian lymph when carefully inoculated, and, of course, reinoculated at puberty, is a perfect prophylactic against small-pox, there seems yet to be a possibility that cow-pox is yet more preservative; nay, it seems to be thought by some authors that one inoculation by animal vaccine would act as a lifelong preservative. This remains to be seen.

Taking all these things into consideration, I think it must be admitted by all that the world owes a debt of gratitude to those Italian physicians who have commenced the practice of vaccination from the calf; and also to Dr Warlomont of Brussels, for his most unwearied perseverance in perfecting the process of Animal Vaccination.

Mr. President and Gentlemen, I thank you for the attention you have given to my paper.

After the reading of the paper, and the thanks of the Society having been voted to the writer, Mr. Victor de Meric, late President of the Society, expressed his great satisfaction with the way in which the subject of animal vaccination had been dealt with by Dr. Drysdale He doubted whether animal vaccination was more permanent in its preservative influence than Jennerian vaccine. In the year 1867, when he visited Paris, and saw the inoculation of calves by Dr. Lanoix, who used to make some fifty or sixty inoculations on the abdomen of the animals, he thought the practice of animal vaccination might prove a great boon, especially in this great metropolis, London. He therefore called and saw Mr. Seaton on his return to London; but that gentleman threw cold water on the idea, and he had hence himself cooled down, seeing that the idea did not seem to be entertained in this country. There can be no doubt, continued Mr. De Meric, that syphilis can be communicated by vaccination. Mr. Hutchinson's cases made a deep impression, and the profession in this country had come to believe in the reality of vaccino-syphilitic contagion. Dr. Blanc, a very competent Indian medical officer, had tried to introduce animal vaccination, at great expense to himself, and established a cow-house near Bedford Square; but this was an experiment that should be made by Government, and not by private practitioners. Suppose there comes an epidemic of small-pox, like what we have passed through of late years, it becomes sometimes very difficult to get reliable lymph quickly. Some persons do not like to take tubes, and it is impossible for the public vaccinators, who have many cases to attend to, to be always as careful in examining the infants as might be desired. So that he did not see why animal vaccination should not be had recourse to in such epidemic times.

Dr. Theodore Williams said that it had struck him during the last epidemic of small-pox that there was no small difficulty in getting reliable lymph for vaccination; and this was certainly a great argument in favour of animal vaccination being added to the State department. Dr. Drysdale had quite exhausted the literature of the subject in his paper.

Dr. Cooke said that, when he attended Dr. Simpson, formerly vaccinator in Tottenham Court Road, he asked him why animal vaccination should not be used. His reply was, that animal vaccination caused far greater disturbance locally and constitutionally than Jennerian lymph.

Dr. de Gorrequer Griffiths had listened with great pleasure to the author's paper. A child was brought to him lately, which had been vaccinated, and from whose arm lymph was to be taken by the public vaccinator. He, Dr. Griffith, at once wrote to the public vaccinator, telling him on no account to take lymph from the infant, as it was syphilitic, and was born of syphilitic parents. The child was affected by herpetiform syphilitic eruption, which appeared shortly after vaccination. In this case, many children might easily have been vaccinated from a syphilitic child. He quite concurred in the advisability of adding animal vaccination to the State department.

Dr. Rogers had only once seen a bad case result from vaccination, and that was the inoculation of a strumous sore by vaccination. It was remarkable what a number of persons of good education still were prejudiced against the practice of vaccination. He thought that Government should take up the question of animal vaccination.

Dr. Drysdale, in reply, warmly thanked Mr. De Meric for his remarks, and for the kind way in which he had encouraged him in proposing that Government should take up animal vaccination. He believed that the idea that animal vaccination excited severer local and constitutional effects than humanised lymph had been shown by Warlemont and others to be quite a mistake. Dr. Griffith's case was similar to some he had met with, and he could quite corroborate Dr. Roger's statement as to the occasional rooted prejudices against vaccination still existing. He had last week vaccinated a young lady, aged four, not before vaccinated, the daughter of a foreign nobleman, who had always resisted the child being vaccinated, until he had shown him the error of his views by conversation.

CASE OF ANEURISMAL HÆMORRHAGE FROM A DISEASED LUNG.

By Kendal Franks, L.R.C.S.I. (*a*)

Dr. Kendal Franks showed a specimen which he had removed from the body of a young man, æt. 22, who died suddenly on the morning of the 5th of January, of hæmorrhage from the lungs. The history of the disease extended over a period of five years, during which period the subject of it had frequent hæmoptyses. The disease originated whilst he was in the employment of a grocer, and he himself attributed it to several severe wettings, and the constant lifting of heavy weights. The first symptom of phthisis of which he was cognisant was a sharp attack of hæmoptysis. Since this he had a cough, which he never completely got rid of. About two years after this he had a second hæmoptysis, which was followed a short time afterwards by œdema of the feet. The third bout of hæmorrhage took place in April, 1874, and was so severe as to confine him to his bed for nearly three weeks. The fourth and last copious hæmorrhage terminated fatally. In the intervals of these severer attacks he had frequently minor attacks of "spitting of blood," the sputa being constantly tinged, besides having frequent epistaxes. In May last a physical examination showed the state of his lungs,

(*a*) Abstract of a communication made to the Dublin Pathological Society, from a shorthand report.

signs of vomicæ being found at both apices. The most remarkable feature then was the position of the cardiac organ. The impulse was strong and distinctly seen between the second and third costal cartilages of the right side, and about two inches from the sternum. The sounds were normal. The boy continued to work as an out-door servant till the 5th inst., when he was discovered lying on the floor in a comatose condition, with a large quantity of blood in front of him, and clots hanging from the mouth. He died within half-an-hour.

About eleven hours after death a post-mortem was effected. On opening the thorax the left lung, uncollapsed, was found to extend a good way across the mesian line towards the right side; the right lung was contracted and firm, and so adherent to the pleura that it was with great difficulty removed. Several large cavities were found in the upper part of the lung. On section, it showed various stages of caseous degeneration; here and there small nodules of calcified matter were met with. The left lung was remarkably emphysematous; cavities were met with in its apex, as well as in the upper part of the lower lobe. With the kind assistance of Dr. Bennett, a careful search was made for the source of the hæmorrhage. In a small cavity, about the size of a walnut, which communicated with another about the size of a hen's egg, a small aneurism was found projecting from the upper wall of the cavity. The appearance of it was very striking, and formed a strong contrast to the wall of the cavity in which it was situated. It was of a pale yellowish colour, except on its anterior surface, where there were some red fungus-looking eminences. In size it was about that of a small pea. The point of rupture, which was situated at the side furthest removed from its attachment, was a narrow slit, about 1-8th of an inch in length. A bristle was passed up through a branch of the pulmonary artery, and it emerged through the opening in the aneurism; another was passed through a small opening close to the aneurism, and was subsequently seen in one of the larger bronchial tubes. Dark coagula were found filling the cavities in this situation, and others were traced in the bronchial tubes leading from this part of the lung and opening into the trachea. The artery upon which the aneurism was situated was one of very small size, though readily allowing a bristle or a small probe to pass. Both lungs were plentifully studded all through their substance with miliary tubercles evidently but of recent occurrence. But one similar case had been laid before the Pathological Society in this country, and that was by Dr. Bennett, in 1871, in which death had been sudden from the rupture of a pulmonary aneurism of the size of a walnut into a phthisical cavity. Attention had first been called to these aneurisms by Dr. Rasmussen, who attributes their formation to the loss of support experienced by a vessel on that side which lies exposed in a cavity, and also to the increased blood pressure occasioned by the obstruction to the circulation in the diseased lung. Dr. Powell, of London, has also shown that an inflammatory change in the wall of the vessel is also a pregnant cause, destroying its elasticity, and necessarily inducing a degenerating process which leads to the gradual yielding of the wall at the point affected.

ON ASSIMILATIVE FOOD. (a)

By W. J. Cooper.

Nutriment properly defined consists of all the various alimentary substances necessary to build up the human body. And as starch forms the greatest proportion of the necessary aliment so starch is in one sense the most important element of nutrition. Some statements have recently appeared to the effect that starch was in no sense nutritious, and if taken alone must lead to starvation. If this argument was intended to prevent people from partaking of starchy foods, it must have been put forward without that careful consideration which the importance of the subject demands. As I stated in a paper read in the Chemical Section of the British Association at Belfast, I once lived for a month upon arrowroot and water, and I have been grateful to starchy food ever since. I should be the last person to recommend such a diet to anybody, or indeed any dietary whatever as a universal remedy for weak digestion or malassimilation of food. Many people have endeavoured to concoct a complete dietary and have signally failed. The only complete dietary known is the milk which the mammalia provide for their young, but even that diet must not be interchanged without caution. If cow's milk be given to an infant child as a substitute for its mother's milk, it should be diluted to the extent of one-half for the first three months of the child's life and one-third for the second three months, and sugar should be added, otherwise it would not be properly assimilated.

Thus it is necessary in this instance to deprive this natural dietary of some of its nutritive properties, and add known quantities of other substances. Starch is as necessary to the structure of the human body as bricks or stones in the construction of a house, and an attempt to build a house of mortar alone or cement alone would be as abortive as an attempt to rear a child upon gluten or nitrogenous matter exclusively. It has been objected to such foods as arrowroot, corn-flour, and especially in the case of corn flour, that the gluten is entirely extracted, and that therefore these finely divided powders are not nutritious. Such objections are somewhat similar to the objections made some years ago to extraction of quinine from bark or morphia from opium. At the beginning of this century opium was known, but its active principle was unknown. And bark, the ancient remedy for ague, was used for centuries before its active principle was found to be quinine. It was imagined that there were hidden and mysterious virtues in the combination which would be lost if a separation was attempted. It is of the utmost importance that medical men should be able to administer exact quantities of any active medicine; and it is of no less importance that invalids and children should be fed with such proportions of assimilable food suitable to their various constitutions. Arrowroot and corn-flour, from the delicacy of their structure, are easily converted into gelatinous and readily assimilable aliments, and the fact that they consist almost entirely of starch enables the doctor or the nurse to admix with other alimentary substances the proper quantity of this nutriment, which forms four-fifths the weight of the food of a large proportion of the inhabitants of the world. There is also another very sound for the abstraction of the nitrogenous matter from corn-flour, it enables the manufacturer to grind it finer and get into a form which renders it, when boiled, gelatinous and digestible. There is no doubt much infantile mortality is caused by ignorance in the matter of children's diet. Some people are in the habit of giving meat to young children. Children should be fed on milk as long as they thrive upon it. But no child less than twelve months old should have anythihg but milk or milk with sugar and water. If people are anxious that their children should thrive and grow up healthy and strong too much attention cannot be given to the matter of their daily food; and great care should be taken that thedainty child has sufficient nourishment.

It is not only that the quality of the food must be good, and the quantity sufficient, but the child's constitution should be studied with the object of ascertaining the nature of the food which is likely to be assimilated. It should be well understood that large quantities of food may pass through the body without nourishing it any more than the odd articles which children sometimes swallow, such as paper, grass, packets of pins, or even street door keys, of the swallowing of which last article I remember an instance. It is notorious that some lean people have voracious appetites, while the fat ones eat comparatively little.

(a) Abstract from a paper read at the Social Science Congress, Brighton.

The reminiscences of the objectionable lump of fat or raw meat of school-boy days, which it was treason to leave on the plate, must be present to the recollection of many people. Fortunately, there was always a boy of carbonaceous proclivity to whom the objectionable morsel could be furtively passed, and who would devour it with the avidity of an Esquimaux.

Too much meat is eaten in this country, and the cattle disease and increasing price of meat may prove a positive benefit if it should prevent some people from eating more than is good for them. Excess of nitrogenous food is believed to be the cause of many of the diseases of the kidneys, which are so prevalent in England. As nitrogen is excreted by the kidneys, those organs, if overworked, will in time degenerate, and not being able to perform their proper functions, their work is thrown upon the other excretory organs, and if they fail blood poisoning takes place, and the victim of an excessive nitrogenous diet is killed as if by an overdose of a narcotic.

The natives of the Sandwich Islands have a favourite food, which they subsist on almost entirely; it is a kind of paste made from the root of the kalo (*Arum esculentum*), a plant cultivated throughout their country. The root when boiled is made into a paste and called "poi." This is the food of all classes of Sandwich society, and according to the wealth of the individual so is the consistency of his food. Knives and forks are not fashionable among the natives of the Sandwich Islands, and they eat "poi" with their fingers. The most expensive kind of "poi" is the thickest, and a sufficient quantity of it can be conveyed to the mouth by one finger; it is therefore called "one-fingered poi." The second quality being more diluted, requires the assistance of two fingers to convey it to the mouth, and that is called "two-fingered poi." The third quality, and most dilute, is called "three-fingered poi." Abyssinians eat raw meat and praise the cordial and warming effects upon the system produced by its assimilation. According to Burton, the Arabs of East Africa say that vegetables cause heartburn and acidity, and Livingstone found that ground-nuts containing oil would neutralise this tendency. One of the most objectionable things that can be given to children are the stimulants or narcotics which are used in enormous quantities in all our large towns. It is of little use to lay down any general rules of diet. Different climates and different constitutions necessitate alterations in dietary. Gardeners have learnt how to supply the food which different plants require for their development. Parents and those who have the rearing of children should study the food which children of differing constitutions require, and secure to them the inestimable benefit of assimilable food, bearing in mind the ancient but literally truthful adage, that "what is one man's meat is another man's poison."

Clinical Records.

DELUSIONS OF THE INSANE.

By J. G. Thornley, M.D.,
Asst. Medical Officer Leicester County Asylum.

It is recorded by Esquirol that there was a female patient at Salpetrière who fancied that she had in her intestines all the personages of the New Testament, and occasionally those of the whole Bible. When she died an examination revealed adhesions of the intestines to the peritoneum and to each other.

In this asylum there was a male patient who had been here for many years, and who for a considerable number of years past was in the habit of stating that there was a a hundred-weight of iron in his abdomen; he would occasionally put his hands to his abdomen, as if to support this weight of metal which he believed to be there, and it was impossible in any way to shake this rooted delusion. He was a strong and healthy man, and was in the habit of working daily on the farm as a labourer. This man suffered from melancholia, was often very reticent, and never communicative. Some time ago he was observed not to take his food so well as usual; he more frequently pressed his hands against his abdomen; and when standing he leaned slightly forward; but he never even once complained of pain or other uneasiness; he was persuaded to go to bed. Afterwards the symptoms increased in severity: the abdomen became very tender on pressure, the appetite failed, and the pulse became weak and thready. During the whole of his illness he was very silent and uncommunicative, so that no information could be obtained by asking him questions. He died a few days after taking to bed, and a post-mortem examination revealed a perforation of the intestine, near the junction of the ascending and transverse colon, sufficiently large to admit the tip of the little finger. Through this opening some liquid fæces had passed into the peritoneal cavity. There were signs of inflammatory action in the neighbourhood of, and for some distance around, the aperture, but not to the extent which might have been expected.

CASES IN PRACTICE.

Reported by John W. Martin, M.D.,
Assistant-Surgeon, Mayfield Factory Dispensary, Portlaw, &c.

Case XIII.—*Pain and Sense of Oppression about the Heart—Area of præcardiac dulness enlarged—First sound replaced by a prolonged murmur—Impulse diffused and weakened—Palpitations—Headaches—Noises in the ears—Dyspnœa—Vertigo—Treatment—Recovery.*

B. H., æt. 30, factory operative, six years married, with but one child, born a year after marriage, presented herself for treatment at the dispensary on the 17th of February, 1875. This patient was tall, well-made, and well-nourished, with a bright florid complexion; her general appearance was that of good health. The following is the history of her case. Previous to her marriage, with the exception of a severe attack of typhus fever some twelve or thirteen years ago, from which she made a good recovery, she had always been a strong, healthy girl. During pregnancy her health remained good. She had a short, favourable labour, perfectly natural. Subsequent to her confinement she noticed her health failing, experiencing, apparently without sufficient cause, a great sense of weakness, and suffering almost constantly from severe headache. In the month of August, 1874, six months before seeking treatment, she was attacked with pain in the left side, under the left breast, and over the whole region of the heart, accompanied by a sense of oppression; this was daily growing worse. The slightest exertion induced severe attacks of palpitation and dyspnœa. If she stooped she was seized with vertigo and singing noises in the ears. At the date of examination she stated that she had no cough, and that the catamenial periods were regular in every respect. Her bowels were confined; she had loss of appetite, and complained much of flatulence, which had however been less troublesome since than before the setting-in of the pain about the heart. Pulse 84, full and hard. The area of dulness over the heart was greatly enlarged, extending five inches downwards from the lower border of the third rib on the left side in the vertical direction, and seven inches under the left breast from the right border of the sternum over towards the left side. The heart's action was slow, regular, and laboured; its impulse much weakened and diffused; the sounds altered. The first sound was lost, being replaced by a long, soft, superficial, and widely diffused murmur, synchronous with the systole of the ventricles. The character of this murmur led me to suppose it was caused by friction. The second sound was heard much more distinctly towards the apex than the base. There was no murmur present at the

base of the heart. The lungs were healthy. She passed about a pint and a-half of water during the day, clear, free from deposit, sugar, or albumen. As treatment I applied a blister over the præcardium, the seat of pain and tenderness, and directed the following mixture to be taken :—

℞ Potass. iodidi, ℥i.;
Potass. bicarb., ℥iij.;
Acid. citric., ℥iij.;
Tr. digitalis, ℥ij.;
Cit. ferri amm., ℥i.;
Sp. am. aromat.,
Sp. chloroformi, aa ℥iss.;
Aqua ad ℥xij. M.

Two tablespoonsful to be taken three times a day.

February 25.—Blister acted well, giving almost immediate relief to the pain and tenderness in the region of the heart. Felt her general health improving. Treatment ontinued.

April 9.—Improved steadily under the above treatment. With the exception of the headaches, from which she still uffered, but less violently than before, there was decided melioration of all the symptoms described when she first ame under notice. There was no longer the slightest enderness to pressure over the heart, or pain in that egion ; the tendency to palpitation, dyspnœa, or vertigo, upon making any exertion, almost gone ; the area of dulness was diminished to a diameter of about three inches in each direction ; the heart's action decidedly improved, the impulse being much stronger than before. The first sound heard very faintly, but distinctly ; it was still marked by the long soft, brushing friction murmur, already described as heard over the apex of the heart. The second sound heard distinctly, both at the apex and the base. Her general health was much improved. In consequence of the continuance of the headaches, I omitted the amm. citrate of iron from her mixture, placing her upon iodide of potass and bark :—

℞ Potass. iodidi, ℥i.;
Tr. cinchonæ, ℥ss.;
Liq. cinchonæ, ℥i.;
Sp. am. aromat., ℥iij.;
Sp. chloroformi, ℥i.;
Infusi cinchonæ ad ℥xij. M.

Two tablespoonsful to be taken three times a day.

April 13.—General health still improving, but thought she must have caught a slight cold, as she felt some return of the pain in the chest. In addition to the continuance of the above mixture I ordered counter-irritation, by means of an ointment containing croton-oil and tartar emetic, to be applied twice daily to the pericardium until the characteristic rash should be produced.

April 26.—Felt much stronger, and better, than she had been for a long time. The headaches were diminished in severity, and recurring at longer intervals. She was able to undergo severe exertion, without the smallest distress. The dulness over the heart still remained, greater, than what it ought to be in perfect health. The friction murmur present, much as before, but no longer masking the first sound of the heart, which was now heard, clearly and distinctly, over the apex, and base, of the cardiac region.

All tenderness to pressure, and pain, gone. Had a good appetite, and felt no inconvenience after meals.

Her treatment was continued.

She asked, and received permission to resume work.

I have no further regular notes of her case, but know, that she still continues to enjoy good health, free from every symptom of the distress, from which she formerly suffered ; and that she is able to fulfil every duty of her occupation as a factory operative.

The following are, I think points of interest, to which I wish to direct attention, in connection with the foregoing case :—

1st. The enjoyment of good health by the patient, previous to the date of her first confinement, with the exception of the attack of typhus, from which she made a good recovery.

2nd. The setting in of the headaches and sense of weakness almost immediately after the birth of her child.

3rd. The absence of any reason to suspect renal affection.

4th. The duration of the headaches, and increasing sense of weakness, for over four years, before the pain under the breast, and, in the region of the heart, made itself felt.

5th. The gradual onset of this pain, unattended by any history of acute inflammation, and its consequences.

6th. The absence of any symptoms pointing to the existence of the rheumatic dyscrasia.

7th. The superficial character of the murmur, and its diffusion over a large area of the heart's surface, supports the idea, that it was not in any way due to valvular disease.

8th. The enlargement of the area of dulness, was decidely over the left side of the heart, involving the left ventricle. The character of the pulse, which was full, and even, and the healthy state of the lungs negative the idea, that the aortic, or mitral valves, were in any way engaged.

Taking these points into consideration, the question presents itself : What was the nature of the case ?

Were the symptoms due to subacute pericarditis and effusion ; or to eccentric hypertrophy of the left ventricle ; or to both these affections combined ?

I am of opinion, that the last of these suppositions is the correct one ; yet there are some difficulties in the way of accepting it, without consideration. The character, and wide diffusion of the murmur described, leave little doubt in my mind, that it was exocardial in its nature, due to roughening of the opposing surfaces of the pericardium. There being no reason then, to suspect valvular disease, to what are we to ascribe the dilatation and hypertrophy, as due ?

That such existed, is rendered probable, by the fact, that the heart's impulse was felt, and seen, over a much wider area than in health. Had the area of heart dulness been altogether due to pericardiac effusion, it would have been scarcely possible to have felt any impulse whatever ; on the other hand, had it been due to hypertrophy pure and simple, the heart-stroke would have been much more vigorous than it was.

Bearing in mind, the absence of any evidence of disease of the aortic valves, how are we to account for the occurrence of eccentric hypertrophy. The following seems to me a probable explanation of the matter.

Previous to the date of her confinement, the patient declared that she always enjoyed good health ; its failure commenced immediately after that event, with the evolution of all the symptoms described. We know that the blood at this time, is laden with effete materials, the products of the process of involution, by which, the womb is restored to its ordinary size, and which, in the usual course of events, are got rid of by the organs of excretion. It does not seem too great a begging of the question, to suppose, that derangement of the excretory functions existed, and that depuration of the blood was not properly performed. As a consequence, spasm of the capillary system of blood-vessels may have been excited, inducing arterial tension, and increased heart action, at a time, when the walls of the last-named organ, were incapable of offering a proper amount of resistance to the opposing force.

Note.—Since writing the above, this patient has again come under my care. She suffers from pain in the region of the heart for the past few days, and headache, together with a rheumatic pain in the right ankle and instep. The enlargement of the area of dulness over the heart permanent ; impulse increased and diffused. A loud single systolic friction murmur heard over the whole extent of the heart's surface, of equal intensity in all parts. She is however able to follow her occupation and is no longer

troubled with the dyspnœa, palpitation or vertigo which were formerly so distressing. The heart stroke is accompanied with very strong *frémissement*. The lungs are healthy. Appetite good. General health fair. I shall watch the further progress of the case with interest.

REPLY OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND TO THE RECOMMENDATIONS OF THE GENERAL MEDICAL COUNCIL.

THE Council of the Irish College of Surgeons have just forwarded to the General Medical Council their "Observations" upon the recommendations of the latter body, of which we reproduce the important portions :—

RECOMMENDATION AS TO PRELIMINARY EXAMINATIONS.

1. That testimonials of proficiency granted by the National Educational Bodies, according to the subjoined list, may be accepted ; the Council reserving the right to add to or take from the list.

Hereupon follows a long list of examining bodies whose examinations are stated to meet the views of the Medical Council, but the Council of this College are at a loss to ascertain the grounds upon which the General Medical Council have arrived at this conclusion, inasmuch as there is no evidence adduced of their having had these examinations inspected and reported upon; whilst, on the other hand, examining bodies of undoubted repute have been omitted from the list.

2. That it be recommended to the licensing boards not to accept the certificate of proficiency in general education from any of the bodies, unless such certificate testify that the student to whom it has been granted has been examined in—

1. English language.
2. Arithmetic.
3. Geometry.
4. Latin.

And in one of the following optional subjects—

Greek.
French.
German.
Natural Philosophy.

The Council of this College beg leave to state that they cannot (in accordance with their bye-laws) accept the certificate of proficiency in general education from any of the bodies whose curriculum does not include "Greek" as a compulsory subject.

REGISTRATION OF MEDICAL STUDENTS.

1. Every medical student shall be registered.

2. No medical student shall be registered until he has passed a preliminary examination.

3. The commencement of professional study shall not be reckoned as dating earlier than fifteen days before registration.

11. Qualifying bodies are recommended not to admit to the final examination any candidate who had not been registered at least four years previously.

With reference to the foregoing recommendations this Council would wish to remark that the history of their College proves beyond question the great importance it has from its foundation attached to a sound preliminary education on the part of candidates for its qualifications ; since the incorporation of this College up to the present date, its authorities having invariably insisted upon candidates for their licence producing satisfactory evidence of a sound preliminary education. With reference to Section 3 of the foregoing recommendations, this College has always encouraged its students to pass a preliminary examination previous to the commencement of their professional studies, and in the vast majority of cases this practice has been observed. Exceptional cases, however, have arisen where it has been considered expedient (and that in the interest of sound preliminary education) to relax the stringency of this rule. Upon such cases this Council feel themselves to be competent judges, and therefore must decline to forego their hitherto unquestioned prerogative in favour of any other authority, as recommended in Sections 9 and 11.

PROFESSIONAL EDUCATION.

3. That it be recommended to licensing bodies that their regulations should be such as to prevent attendance upon lectures from interfering with hospital and clinical study.

The Council of the College state that the regulations in force in this city have always been such as to prevent the possibility of any interference similar to that alluded to.

PROFESSIONAL EXAMINATION.

6. That not less than two examiners, or one examiner with an assessor, should be present at every oral examination.

The Council of this College have had their bye-law altered with the view of having two examiners present at each candidate's examination, by which regulation each candidate, at his oral and clinical examination, undergoes the ordeal of eight examiners.

7. That the oral examinations should be open at least to members of the examining body.

The examinations of the College have always been open to its fellows and licentiates.

10. That excellence in one or more subjects should not be allowed to compensate for failure in others.

11. That if a candidate be rejected for failure in any one subject, he should be re-examined in all.

If the candidate fails on any one subject at either of the written or the viva voce examinations, he is not allowed credit for the examination, and on coming up again must be re-examined on all the subjects comprised in that group.

12. That examiners should only be elected for definite periods, with power of re-appointment.

The examiners of this College hold office for the term of one year only, but are eligible for re-election.

15. That licensing bodies should distinguish separately in their returns the names and numbers of candidates examined, and the numbers of those passed and rejected.

The wording of this recommendation seems very obscure. The habit of this College has been to furnish the General Medical Council with the names of the candidates passed and the number, but not the names, of those rejected, a practice from which this Council sees no reason to depart.

17. That in the case of certificates presented before admission to examination, each should include a statement from the teacher that the candidate had satisfactorily attended examinations from time to time held on the subject of study to which the certificate relates.

The College Council are of opinion that every candidate should have his merits decided upon by his several examiners on such evidence as he affords them at the time of his examination. They cannot, therefore, approve of any extraneous influence being brought to bear on such decision.

20. That it be recommended that in no case should the examination of a candidate by any of the licensing bodies in any subject be conducted wholly or in great part by the lecturer or teacher in that subject in the school in which the candidate has been educated.

The examiners of this College cannot, according to its charter, whilst they hold office, be either lecturers or teachers.

22. That it is desirable that candidates in examinations in anatomy should understand that they may be called upon to perform actual dissections, and that candidates in examinations in surgery should understand that they may be

called upon to perform one or more operations on the dead subject. (Minutes of General Council, June 22, 1875, p. 54.)

With reference to this very mild expression of opinion upon the part of the General Medical Council, the Council of this College regret extremely that it is not of a more mandatory character. Such methods of testing candidates for their qualifications have been for some time in force at their several examinations, and have proved themselves in every respect to be attended with most beneficial results. No doubt difficulties can be alleged as existing in the way of carrying into effect this much to be desired reform.

REGISTRATION OF WOMEN.

On Friday the Duke of Richmond and Gordon received at the Privy Council Office a deputation of ladies and gentlemen interested in the question of the registration of properly-educated women as practitioners of medicine in terms of the Medical Act of 1858. The deputation included Lord Aberdare, Mrs. Garrett Anderson, M.D., Miss Baily, Dr. King Chambers, Mr. Forsyth, M.P., Miss Jex-Blake, Mrs. Pennington, the Right Hon. J. Stansfeld, M.P., and the Dean of the London School of Medicine for Women.

Mr. Stansfeld introduced the deputation as representing the London School of Medicine for Women. The object was to ascertain the intention of her Majesty's Government with reference to this question. Certain ladies had already spent much time and much money in preparation and study for the profession of medicine, and every year that passed added to the loss and injustice which they had already suffered. He believed that the question had now passed beyond the phase suitable to legislation by a Bill introduced by a private member, and that the time had come for action on the part of the Government. The question now was what that action should be. In answer to an inquiry addressed to his noble friend Lord Sandon, he had been informed last session that the Government would consider the matter during the recess, and the present deputation was anxious to learn the result of such deliberations. The letter addressed by order of his Grace to the President of the Medical Council had occasioned a three days' debate in the Medical Council, and at its close they reported in reply that they were "not prepared to say that women ought to be excluded from the profession."

Mr. Forsyth, M.P., specially desired to draw attention to the fact that no law prohibited the admission of women to the medical profession. The Act of 1858 contemplated the admission to the Register of all persons who had complied with certain conditions. The word "male" did not once occur in the Act; but a certificate of competency was required, and the 19 examining boards by whom such certificates were granted had, it seemed, combined to refuse to examine women with a view of ascertaining their competency for practice.

Dr. King Chambers felt sure that the Government could now deal with this question with less difficulty than at any previous time. The prejudices of medical men on the subject were gradually diminishing, and the study of medicine by women was becoming more generally popular. A majority of the medical journals were now either in favour of the women or at least neutral. This change of feeling on the part of the profession would certainly render the action of the Government easier.

Mrs. Garrett Anderson explained that the only body that did not profess to be able to exclude women was the Society of Apothecaries, and they practically refused them admission, inasmuch as they would only examine those who were educated at the public medical schools, from which women were excluded.

Lord Aberdare said on all sides there seemed a resolution to shut out the women. He might remind the Lord President of a certain room in the South Kensington Museum which was expressly set apart as a refuge for those women who had been driven forth from the china painting works at Stoke by the jealousy of the male china painters. He confessed that the injustice under which these women suffered seemed to him no greater than that now complained of. He trusted that the Government would follow up the course they had begun by the letter to the Medical Council, and he could assure the Lord President that strong support would not be wanting from those on the opposite side of the House.

The Duke of Richmond and Gordon expressed his gratification at receiving the deputation, and his sense of obligation for the clear manner in which the facts had been laid before him. It was true that the Government had the matter under consideration, but he could not at that moment state the course which they would ultimately adopt. He quite saw the force of all that had been put forth by Mr. Stansfeld, and by Lord Aberdare, but he could not a present announce a distinct line of action. The question seemed in the first instance to rest with the examining boards, as if they consented to admit the women, *cadit quæstio*, the need for legislation would disappear

Lord Sandon inquired whether he correctly understood that no special privileges were desired, but merely the removal of special disabilities.

Mr. Stansfeld replied that this was exactly the case, and that if only women were placed on an equality as regarded examination and registration, the friends of the movement would see that all other facilities, such as hospitals, were provided if necessary.

Miss Jex-Blake remarked that on the other hand it had never yet been decided that any of the examining boards had the power to refuse to examine women. It was true that they had assumed that power, but it never had been conceded to them by any legal tribunal, except in the case of the Scotch Universities, where a decision was given by a bare majority of the Lords of Session, and on quite different grounds.

Mr. Forsyth urged that the Bill should be a general one, including all the examining bodies, and referred to the fact that the Scotch Universities Bill had been opposed on the plea of its limited application.

Lord Aberdare then expressed his opinion that the true way of meeting the difficulty would be to require all the nineteen examining bodies to examine candidates without distinction of person, just as the Act of 1858 expressly bound them to examine all candidates irrespective of their holding or not holding certain medical theories.

The Duke of Richmond and Gordon having promised his best attention to the subject,

The deputation then withdrew.

Parliamentary Intelligence.

MR. GATHORNE HARDY'S ARMY MEDICAL SCHEME.

Mr. Gathorne Hardy, in introducing the army estimates, entered *in extenso* into the changes which he proposed to make in the Army Medical Department. He thought the time had come when he ought to pronounce his opinion on the question of general or regimental hospitals, and he had come to the conclusion that the idea of going back to the regimental system after what had been done was simply out of the question. It was impossible that it should be done without making rearrangements and alterations which never could work in time of war. The system which he had approved enabled them to apply forces at the places where they were wanted, whereas under the regimental system they were bound to have medical men in particular positions where they might not be wanted. By the control which could be exercised they could have a larger consulting staff, they would be able to select the best operators and the best physicians, and they would have larger means and appliances than was possible under the regimental system. He believed that the effect of all these advantages would be that the health and efficiency of the soldier would be improved. He could not help saying that this system seemed to bring more immediately under the eye of the chiefs of departments every one qualified to rise; that it would tend to make the Medical Department more efficient—although he was far from saying that it was not efficient—and enable promotion to go on; and that it would enable them to pass by those who did not wish to go forward without the necessity of bringing them forward in the hope of obtaining that to which they would be entitled if they continued to serve—namely, a pension. There were two points that were brought prominently before him with respect to the

Medical Department—first, the want of candidates to enter the service; and, secondly, the want of promotion for those who were in it. These points he hoped to meet by the scheme he was about to lay before the House. He approved, then, of the general hospital system, and he ventured, with great distinctness and plainness, to say that he was not prepared any longer to listen to complaints on that subject. He had come to a conclusion upon the subject, and it was a conclusion on which he meant firmly to act. His new scheme was this. He proposed most liberal terms. The candidates who would have to undergo a severer examination would, on entering the service, have 250*l.* a year from the beginning, and at the end of ten years they would be presented with 1,000*l.* on leaving, and the heads of the Medical Department would have the power of selecting from among them such a number as would be sufficient to fill the vacancies in the higher ranks and to keep up the flow of promotion. That might be regarded as being a very dear system, but he believed it would ultimately be found to be a cheap one. In the first place, much less would come upon the non-effective vote, and in the second place the mobilisation scheme would be assisted by the fact that there would be numbers of medical men who would be able to act upon an emergency, and, who, although, because of being married or from other causes, they might desire to retire at the end of ten years, yet would continue to retain their military predilections, and would not regret to find themselves again among their old comrades. Then, the sum of 1,000*l.*, though not a very considerable amount, was one which might enable a man to purchase a practice, while it would be known throughout the country that the service was a good service, that the pay was fair, and that it opened to those who were clever and skilful in their profession, the prospect of promotion by selection. But, in order to carry out the scheme fully he must go a step further, and he proposed that those who went on after the ten years, for the first two years should have their pay increased and should have 17*s.* 6*d.* a day; that at the expiration of twelve years they should become Surgeon-Majors with 1*l.* a day, and that five years after that they should have 1*l.* 5*s.* per day. Thus, by diminishing the supply below, too many would not be brought into the upper ranks, for it was a mistake to suppose that by tapping the top way was made for everybody below, for the body of a bottle was a great deal larger than the neck. He should not on the present occasion enter into details, which would appear in the warrant in due course; but he might mention that if a man during his ten years of service should, from sickness or otherwise, require a provision at certain periods, he would receive a portion of the 1,000*l.*, so that he would not go away as a pauper, but as a man who had done something for his country. The medical officers then would have 250*l.* a year for ten years, 320*l.* for two years after that, beyond that time they would have 365*l.*, and after five years more 1*l.* 5*s.* a day, or 456*l.* a year, A good prospect would, therefore, he thought, be held out to them, and for those who went on in the service there was rank, money, or pension, and distinction by selection. As things at present stood the medical schools did not, he was sorry to say, send up some of their best young men to the examinations for the Army. There were forty-five vacancies, for which there were only twelve candidates, and they were obliged to take some candidates who had been previously rejected, and he was opinion that it was very undesirable that a class of medical men whose atttainments might be said to be low should be placed in a very difficult service, in which they would have great dangers to encounter. He proposed, he might add, that the Surgeon-General and the Deputy Surgeon-General should retire at the age of sixty instead of sixty-five, and that their retirement should be compulsory, without any exception, for the making of exceptions only tended to all sorts of inconveniences. Great pressure was sometimes put on the Department to retain men under special circumstances, but it was better that they should receive just compensation for the net loss the might sustain, as in the present instance by the substitution of the age of sixty for sixty-five. He hoped the committee would see that the proposal which he had sketched was a fair one. The non-effective vote would of course be increased by the fact that a certain number of men would have to retire at the age of sixty, and it would go up for a certain number of years, but it would then begin to diminish again, Up to 1880 it would, he thought, practically remain at about the same point, £90,000 or £91,000. The effective vote, which was about £200,000 this year, would vary also; but if the system of which he spoke went on it would in 1912 be £150,000 instead of £200,000. He could not, he might add, hope to please everybody; he had long ago given up the idea. As for pleasing all the members of the medical profession, that also was a thing he was afraid he could not accomplish. He had read a great many pamphlets on the subject, and he had been very slow in arriving at a conclusion with regard to it; but every sort of scheme had been tested by calculations, and he must say that that which he had first laid before the committee seemed to him to be the most effective, and likely to be [the most beneficial to the soldier. By its means talented, earnest, and able men would, he believed, be induced to enter the army, some of whom afterwards the heads of departments might feel justified in promoting to very difficult situations.

WEDNESDAY, MARCH 8, 1876.

THE ATMOSPHERIC GERM THEORY OF DISEASE.

We gather from Professor Tyndall's later contributions to the columns of our contemporaries that he, at least, is firmly impressed with a belief in the atmospheric germ theory of disease. He now reproduces a letter from M. Pasteur filled with protestations of gratitude to one who has brought "the high authority of his philosophic mind" to bear upon views which so entirely accord with his own. It is almost unnecessary to say that both before and after M. Pasteur published his results on the germ theory in 1863 that numerous investigations were made to determine the ultimate nature of the floating germs of the atmosphere—of that dust which constitutes the

"cloud of witnesses" to the truth of Professor Tyndall's theory. No new light has been shed upon the discussion; it has been long known that the atmosphere contains fragments of organic and inorganic matter varying to an appreciable extent in different localities; so much so, as to enable careful observers to say whence the dust was collected. But, although these constituents of the air vary in different localities, the infusorial life produced is nearly always almost identically the same. M. Pasteur is a chemist, and, by his published writings, we learn that he contents himself by employing a magnifying power of 180 diameters for determining the nature of the atmospheric dust and the contents of his infusions. It is by no means surprising that he concludes, in a confident tone, that "Elle est inattaquable cette conclusion qui j'ai déjà formulée dans l'état actuel de la science, l'hypothèse de la génération spontanée est une chimère," for he evidently looked for his "witnesses" in the shape of cheese-mites rather than in "the finest ultra-microscopic particles" spoken of by Professor Tyndall, and amongst which we shall find "the matter potential as regards the development of bacterial life." But Professor Tyndall does not care to enlighten us too much on this point, for while he asserts again and again that 139 flasks were "sterile," he only mentions the examination of one infusion of turnip in which "no amount of searching with the microscope could reveal the trace of a living bacterium." It is absolutely necessary we should know what magnifying power was used to ascertain this, for it will not be denied that nothing short of a power of two or three thousand diameters will enable microscopists to link particular forms with special effects. For determining the precise characteristics of the various objects taken in the air so that we may hereafter identify them, and connect them with a deranged condition of health a much higher power than that spoken of by Pasteur is absolutely required. Dr. Beale is therefore perfectly justified in asking for further evidence of the sterility of Professor Tyndall's flasks, for histologists, and not a few medical men, are not quite convinced that a few hundreds or thousands of bacteria in a clear fluid or atmosphere might not be made manifest by the magnifying power we have indicated. For the detection of the lowest forms of life, not only the highest powers of the microscope, but also the most skilful illumination, is required, and it is almost unnecessary to say "multitudes of bacteria may exist in a fluid that has not fallen into a state of 'rottenness,'" or in one "muddy, having mould above and slime below." In fact, until some kind of chemical or mechanical disturbance has taken place in the infusion, bacteria and the smaller forms of organic life will enjoy a *still* state of existence, float in a very fine, pellucid film on the surface of a fluid, or become encysted and fall in an amorphous, impalpable condition to the bottom of a flask; in either case a "searching beam" of light sent through them will not detect the smallest trace.

It is perfectly obvious, therefore, that the various substances contained in any particularly prepared infusion must remain to some extent in a state of molecular combination, forming compounds with the water, and which no "searching beam" would detect or demonstrate. If, however, minute atmospheric germs retain the power of setting up putrefactive changes, it must be admitted they also have some sort of structural characters, probably approximating closely to the state of minute spheres, molecules consisting of water and albumen. If microscopic power is unequal to the detection of such bodies, chemistry should certainly be quite equal to the task; and as Mr. Sorby observes, "the relation between the size of the ultimate particles of living matter, capable of propagating itself, is manifestly a question of the very greatest importance in connection with the atmospheric germ theory of disease." Admitting, then, that these ultimate molecules are larger than they are imagined to be by Professor Tyndall, there are other and serious objections to his theory, for these bacteria and monads, we learn from Professor Huxley, present a great variety in form, and no doubt their chemical and structural arrangements must equally differ, but if the test tube and the microscope should both prove unequal to the task of determining this, we should think it scarcely possible to offer an opinion upon, the final velocity with which such extremely minute molecules of matter would subside in air, or even in "wooden filter boxes" not air-tight; at all events, we may conclude it would be so slow, that they would require years, and in the meantime they would certainly penetrate into every place to which air has excess.

The idea that minute atmospheric germs were the cause of diseases, as well as putrefactive changes, is no new theory; it originated with Kircher and the pathologists of the seventeenth century. Since their time it has been frequently revived, and hundreds of more carefully conducted experiments than those made in their days have certainly done very little towards confirming it in the minds of the profession. The late Professor Hughes Bennett and his able assistants conclusively proved the fallacy of the theory; in fact, their numerous experiments indicate that the production of infusorial life depends, for the most part, upon temperature, chemical constitution, density, and other equally important physical properties of the air, rather than on living floating organisms. Nevertheless, in Professor Bennett's series of experiments, as well as of other observers, it has been noticed that there were exceptions to the general rule, and these Pasteur and Tyndall attribute to currents or limited portions of air being richer in germs, whilst others are free from them. But that this explanation applies generally and especially to the experiments of Dr. Bastian and those who agree with him is not at all probable, nor does it at all enable us to say whether it is or is not "possible to remove parasitic diseases from the earth."

HAYES COTTAGE HOSPITAL.

A NEW building for a Cottage Hospital has been recently opened in the village of Hayes, near London, in the presence of the most influential inhabitants of the neighbourhood.

After the usual ceremony had been observed, the treasurer, in a few remarks, stated that the total cost of the building was £525, of which about £50 was yet owing. The sum was at once collected or promised.

The hospital is substantially built with 14-inch walls, and yellow bricks, relieved with red brick, stone and

terra cotta, and the roof is covered with tiles. The building faces towards the south, and the accommodation on the upper floor consists of two wards for two beds each, and a nurse's room between, with inspection windows while the ground floor has a special case ward, dispensary kitchen and day-room, back-kitchen, larder, large linen closet and store place for baths, &c., with soft-water pump There is also a shaft from the upper floor to the back kitchen for dirty linen. Great pains have been taken to provide a good system of ventilation for the comfort and health of the patients, air-shafts being placed in the angles of the wards, and the windows being formed so as, if required, to admit air at the meeting rail without creating an aperture elsewhere. There are also ventilators in the ceilings, and a good entrance and staircase in the centre give ready access and add to the airiness of the building. Both the day room and the back kitchen are fitted with good cooking ranges, with ovens and large boilers. These boilers have feed-cisterns attached, which are supplied by pipes from a cistern connected with a pump in the back kitchen, and so arranged that no water can be drawn from the pump unless the boilers are charged. There are likewise a well of good water and a large rain-water tank. The grounds (in a corner of which is a small mortuary) are enclosed with brick walls, the front being dwarf and the upper part in open timber-work corresponding with the two wide gates.

The site was the gift of Sir Charles Mills, Bart.

The hospital is intended for the benefit of poor persons resident in the parish of Hayes who may be suffering from accident or non-infectious disease, and who cannot be properly attended in their own homes. Cases of advanced consumption or hopeless chronic disease cannot be received.

Patients are required to pay, in advance, from 2s. to 7s. per week, according to their circumstances ; the amount in each case to be decided by the Working Committee, in conjunction with the patients' employers or friends. Cases of severe accident or emergency are received without a recommendation.

The medical officer to the hospital is Mr. Edward Parrott, of Hayes.

We wish the managing committee every success. Our views are greatly in favour of cottage hospitals. Thousands, we might say tens of thousands, of cottagers, the majority of whom are in a position to pay their expenses if received into a cottage hospital, die annually from the want of properly prepared food and proper nursing, and from the complications of disease induced by the draughts from which no cottage is free. Every village might have its cottage hospital, and the expenses could be mainly defrayed by club arrangements among all the cottagers around. Just as now labourers pay a small annual subscription in order that they may have the services of a medical man in time of sickness, so might a small subscription gain for them the advantage of hospital accommodation, provided that the managing committee and the medical attendant were of opinion that the case was a fit one. Employers of labour would all be willing to co-operate in such a movement, for they too would be gainers.

Such institutions should not have any special medical officer; on the contrary, any patient admitted should have the opportunity of being attended by the practitioner who would have attended him had he remained at home, and the practitioner should receive remuneration as though attending the patient at his own residence.

Cottage hospitals under such management would be of immense value to the community, for it must be admitted that the hard-worked country practitioner finds no scientific attraction in the case of a poor labourer in a damp and wretched hovel dying under circumstances which cannot be controlled by any skill or knowledge which he may possess ; but if those same cases were under treatment in a well-managed hospital they would become a source of instruction from which the ablest medical practitioner could not but derive benefit, and in turn the knowledge so obtained would be brought to bear upon the treatment of disease in the higher classes.

We recommend the importance of cottage hospital accommodation to the consideration of those who manage the affairs of the many wealthy club charities, for it is not our desire to increase medical charities, many of which are at the present time grossly abused, but to call the attention of the poor to a means whereby they may be enabled by a moderate saving to alleviate their suffering and prolong their lives.

THE MEDICAL COUNCIL AND THE IRISH COLLEGE OF SURGEONS.

We publish elsewhere a lengthened abstract of the reply of the Irish College of Surgeons to the recommendations of the Medical Council. With most of these recommendations the Council of the College is already in accord; but there are others from which it dissents, and respecting which its views will demand the consideration of the Medical Council when it meets.

Firstly—As regards preliminary education, the College demurs to recognise the long list of outside examinations of the merits of which they know nothing, and the Medical Council probably almost as little, and they decline, moreover, to accept any examination which does not include Greek. This tends all in the direction of a high-class general education for its Licentiates ; but the College moves quite in the opposite direction, and lowers its academic position by continuing to permit its candidates to pass their preliminary examination at any time before they become Surgeons. As a matter of fact, few students do postpone their preliminary until the eve of their qualification, but the College permits them to do so, and declines to accept the recommendation of the Medical Council, or to follow the example of all respectable surgical licensing bodies; thus sanctioning the student in proceeding with his medical studies before he has shown that he can read, write, and cipher, or translate a prescription. No doubt the Council of the College is compelled to a laxity in this matter by the competition of the Queen's University, which—as is the wont of that august body—is the only University and almost the only qualifying body in the United Kingdom which recognises medical studies before proof of general education. It is impossible that the Medical Council can exercise any pressure upon other licensing bodies until they have dragged the Queen's up to a moderate educational level. As regards the enforce-

ment of practical examination in dissection and operative surgery, the College expresses a very strong opinion, in which we most cordially concur, and we trust that the Medical Council will make the effort to induce the Scotch Colleges to reform their examinations in this respect. It is futile for the northern representatives to say "it can't be done" now that the Irish College has shown them the way to hold a *bonâ fide* test of operative proficiency. "Where there's a will there's a way;" and if the Scotch bodies had a mind to it, they could do it.

Notes on Current Topics.

The Medical Department of the Army and Navy.

Our contemporary representatives of the interests of the Army and Navy manifest much interest and sympathy with the medical grievances of the service. The *Broad Arrow* observes, with reference to this very important matter:—

"The break-up of the regimental system in the Medical Department of the Army is likely to be evidenced in an additionally forcible manner sooner than we expected. In our remarks the other day we alluded to the wholesale severance of medical officers from corps which, under the present unpopular *régime*, may be anticipated in 1878; but a blow of a like character is yet nearer at hand, unless by good chance the forthcoming warrant should avert it. The appointments to brigade depots were some time ago fixed for three years on the apparently justifiable ground that being home berths the tenure of them should be shorter than that of 'attachments' to regiments; but, though it is well a difference between the two classes of appointments should be observed, the brevity of regimental 'attachments' makes those of brigade depots short indeed, and on the 1st of next month a large number may be expected to fall vacant. The consequent evacuation will be a foretaste of what is to follow two years hence, and, doubtless, this fact alone will serve, together with the pressure which is now being put upon the Secretary of State, to ensure the adoption of some medium course between the extinct regimental system and its unworthy, inefficient, and unpractical substitute."

Hospital Saturday.

The second meeting of the newly-elected Council and Committee of this Fund was held last week in the board-room of the London Hospital, which had been kindly lent for the occasion. The chairman, Capt. Mercier, expressed the gratification he felt that the authorities of both King's and the London Hospitals had recognised the usefulness and importance of the Saturday Fund by lending their rooms for the purpose of meetings; he had no doubt that when the request was made others would follow the example. He also announced that Messrs. Milner had presented the Fund with an iron safe for the keeping of their books and effects. Dr. Ambler's resignation as Hon. Sec. was accepted, and a resolution was carried appointing a paid secretary at £150, and an organising agent at £130 per annum. The most important business of the meeting was the decision with regard to the day of collection. The idea that it should take place on the Saturday immediately preceding Hospital Sunday was negatived, so to avoid the possibility of misconstruction; and the "First Saturday in September" was finally decided as Hospital Saturday for 1876.

Charing Cross Hospital.

By direction of the Council of Management this hospital will be closed from the 15th of March till the 1st of May, for important alterations to the building, which, when completed, will add greatly to the comfort of the patients, and to the number of beds at the disposal of the authorities. No patients can therefore be received during the period mentioned, nor can any patients be received after this date, except such cases as can be relieved by the 15th of March. On the 1st of May 30 beds will be opened for the reception of accidents and urgent cases. On the 1st of June about 75 more beds will be opened for general cases, including a ward for children, and it is expected that in October the number of beds will be increased to 200.

To enable the Council to meet the enormous expense connected with these important alterations and additions, it appeals for funds to a generous public, which will we trust not be slow to recognise the value of such an institution to the poor, and for the advancement of medical science.

Hydrophobia.

Last week a boy 14 years of age was admitted into St. Mary's Hospital, London, under the care of Dr. Broadbent, suffering from all the symptoms of hydrophobia. He was immediately treated with large doses of hydrate of chloral, and the paroxysms became less frequent and less severe. It is now ascertained that he and another boy unknown were bitten by a dog some few months back, and the scar upon the finger still remains. The case is beyond a doubt one of hydrophobia, and, regardless of the ultimate result, is rendered of extreme interest and importance by the peculiar course followed by the symptoms.

The Effect of Colours on the Mind.

A Dr. Ponza, the Director of the Lunatic Asylum at Alessandria, in Piedmont, has suggested and is carrying out the use of coloured glass in the windows and in the ornamentation of the rooms as a treatment of lunacy. The *Daily News* gives a humorous article upon the effect of certain colours upon the minds of men—green and orange to arouse theological bitterness; blue and buff to set a whole constituency raving; and red to drive all roughs mad; and it adds, "it is difficult to avoid feeling sceptical about some of Dr. Ponza's lunatics. The gentleman who declared himself quite recovered after a night in the violet room was very properly refused permission to return to the bosom of his family. A yellow paper might have set him off again, or he might have imitated an unfortunate artist of promise, who conceived such a hostility to black that he smashed in the hats of all his friends." It is too much to expect to cure or even to relieve lunacy by confining a patient in a room in which the light falls in shades of violet or of any other colour; but still the surroundings of a man tend to elevate or depress his spirits, and among those surroundings colour and light play an important part. In a climate

like that of England, where during so many months in the year the sun scarcely makes its appearance, the study of colour in decorations might be made to serve a useful purpose. Many hospital and sick asylum wards are stained with the notoriously depressing buff or brown wash, and if such were replaced by a violet or light grey tone, we doubt not that many a sick or convalescent patient would be found to declare, like Dr. Ponza's lunatic, that he was decidedly better, if not *quite* recovered.

The Assessment of St. Thomas's Hospital.

A QUESTION of considerable interest to hospital authorities was decided at the Court of General Assessment Sessions last week, the overseers of Lambeth having appealed against the assessment of St. Thomas's Hospital. In 1872 the Court reduced the rateable value from £17,580 to £10,900, and the same figures have been now fixed upon. The overseers could not understand why the assessment of this hospital had been reduced, and now sought to have it raised to its original standard. On the part of the hospital it was contended that in consequence of the high rating five wards of this hospital were closed and 140 beds empty, which was something like refusing admission to 1,200 patients every year.

After hearing counsel on both sides, the Court decided that the reduced rating of 1872 was the more equitable, and must be adopted. We congratulate St. Thomas's on the result, albeit we would rather see the rating of hospitals removed altogether.

Public Analysts.

IN the House of Commons on Friday last, a weak point in the Adulteration Act was selected by Mr. W. Williams to draw out an official opinion upon the anomalous position in which the appointment of public analysts is found in some districts.

Mr. Sclater-Booth stated in reply that so far as he knew there were 34 analysts appointed in the counties, and 42 in boroughs; but he had no means of knowing in how many cases arrangements had been made by which analysts could be supplied from adjoining districts as provided by the Act. He was not aware that no practical result had followed from the act owing to the absence of any provision for the payment of a salary to the analyst; no doubt practical results had not followed in all cases, but that was principally from the impossibility of employing the police previous to the Food and Drugs Act of last session; but he hoped that this evil would be remedied. He should be glad if the case was made out to put in force the powers for the compulsory appointment of analysts' but he had no information to induce him to think that the time had arrived for the exercise of such powers.

We regret that Mr. Williams had not taken the trouble to satisfy himself with sufficient data so as to have prevented the expression of such an evasive and unsatisfactory reply from the Government.

Army Medical Department.

IN his statement on the Army Estimates, Mr. Hardy has finally pronounced for the retention of the general staff system as more economical and efficient, and because by the power of selecting officers for positions suitable to them as physicians or surgeons the health and efficiency of the army would be improved; and he asserts with great distinctness "that he is not prepared any longer to listen to complaints on this subject." For the various grievances alleged he proposes a short service system, giving candidates who have passed a severe examination £250 for ten years, with £1000 at the end of that period if not selected for vacancies on the permanent establishment. All administrative officers are to be compulsorily retired at 60 years of age without exception. We shall enter more fully into the question next week.

The Medical Inspectorship of the Irish Local Government Board.

WE have good authority for the belief that the feeling of the profession in Ireland, as expressed through the Council of the Irish Medical Association, and by the MEDICAL PRESS AND CIRCULAR, as well as by influential individuals of its members, has decided the authorities to appoint a medical man to the Inspectorship vacant by Dr. Croker King's promotion. The selection made is pretty well known, but we feel it to be premature to state the name of the gentleman who has been chosen. The following memorial has been forwarded by the Committee of the Council of the Irish Medical Association to his Grace the Lord Lieutenant, under the apprehension that the Government might imagine that medical men were indifferent upon the subject, or might be still undecided as to the necessity for appointing a medical man:—

MEMORIAL.

TO HIS GRACE THE DUKE OF ABERCORN, K.G., LORD LIEUTENANT AND GOVERNOR GENERAL OF IRELAND.

The Memorial of the President, Vice-Presidents, and Council of the Irish Medical Association,

Sheweth,

That your Grace's memorialists have become aware of a public report to the effect that it is in contemplation to appoint to the office of Inspector under the Local Government Board, in the room of Dr. Croker King, a person who is not a member of the medical profesion, and who has received no special education in medical or hygienic science.

That, for nearly thirty years since the creation of this office by the Poor Relief (Ireland) Act of 1847, a certain number of the Inspectorships have always been held by duly qualified medical practitioners, it having been the intention of Parliament that the Commissioners should have the advantage of sufficient professional advice and assistance in their administration of the medical charities and the Poor-law medical relief system of Ireland, which intention was recognised and carried into effect for a period of more than a quarter of a century.

That by the various Poor Relief, Medical Charities, Vaccination, and Public Health Acts, and by the regulations made under the authority of these Acts, the Inspectors under the Local Government Board are charged with the inspection of drugs and with the supervision of more than one thousand medical officers of workhouses and dispensaries, both in their capacities as such and as sanitary officers as well as public vaccinators, and are frequently called upon to hold sworn inquiries, and to make reports upon charges of neglect of medical duty, upon which no person can form a competent opinion except a duly qualified medical man.

Your Grace's memorialists respectfully submit that to

entrust such supervision to any person not possessed of a special knowledge of those duties or of the surgical questions involved in such charges would be detrimental to the service, and unjust to the medical officers who are subject to such supervision, and are, moreover, liable to severe penalties upon the authority of the report of such Inspector.

That the Irish Poor-law Medical Department deals with numbers of sick persons, far surpassing that of either Medical Department of the Navy or Army with a medical staff larger than that of either service, and with an expenditure almost equalling that of the Army Medical Department, and three times that of the Naval Medical Department.

That within recent years the functions of Inspectors in connection with the medical and sanitary services of Ireland have been greatly increased in consequence of the wide extension of the medical charities system; and, furthermore, new duties of the greatest importance have been entrusted to them in connection with the public health of the country, which is administered by the workhouse and dispensary medical officers; and your Grace's memorialists respectfully submit that the necessities of the services indicate rather an increase in the medical inspecting staff of the Local Government Department than any curtailment, especially as in our short experience of the working of the sanitary system many questions have arisen which would need a special professional knowledge for their adjustment.

For these and other equally weighty reasons your Grace's memorialists respectfully request that, if the selection of a non-medical inspector in the room of Dr. Croker King be in contemplation, your Grace's assent will not be accorded to such appointment, and your memorialists pray the exercise of your Grace's authority to prevent such a policy being carried into effect in future.

Signed on behalf of the Memorialists.

The Opium Trade.

A DEPUTATION, headed by Lord Shaftesbury, and including several Members of Parliament from the Anglo-Oriental Society for the Suppression of the Opium Trade, waited on the Marquis of Salisbury, urging upon the Government the desirability of restricting the opium traffic in China and the Indian Archipelago. The noble Marquis pointed out the great financial difficulties in the way of abandoning the existing system of collecting the revenue, which, he said, restricted rather than encouraged the growth of opium. He promised, however, that the matter should receive the attention of the Government.

Excerpta Medica Ridicula.

WE clip the following from a north of Ireland paper:—

"A REPTILE IN A COW'S HEART.—The other day a cow, after labouring under some peculiar disease, died, and on being opened, it was found that the heart was larger than usual. It was consequently opened, when an animal resembling an eel in shape, measuring about three inches in circumference and six inches in the body, with a tail split up into fibres, was found occupying the centre cavity of the heart. That organ was, indeed, nothing but a shell, the creature, *which had a nose and ears like a squirrel*, and seemed to be almost entirely composed of blood, having eaten and appropriated the whole of the interior of the distressed animal's heart."

Diet Cure for Intemperance.

DR. TURNER, of New York, writes to Mr. C. O. Groom Napier, who read a paper last year upon the above subject, to inform him of miraculous cures of intemperance made by him by means of a vegetable diet. We have been requested to publish the letter, but we think it sufficient to comment upon one or two of the chief statements. Dr. Turner, after referring to two brothers whom he cured and restored to society, observes that he has since treated upwards of 1,000 cases of intemperance by vegetable diet with marked success, in a majority of instances, and that he has made notes sufficient to fill an octavo book of six hundred pages. It is his intention to prepare a paper on "Vegetarianism as a Certain Cure for Intemperance," to be read at the British Association next year. We agree with Dr. Turner that intemperance is the most monstrous evil that afflicts society, and had almost hoped that there might be some real value in the treatment suggested; but as his book is to contain notes on the cure of cases of consumption, cancer, and some other supposed incurable diseases by the same treatment, we cannot but conclude that his evidence is wholly unreliable.

Brighton and the British Medical Association.

AT a numerously attended meeting of medical men recently held, a resolution was passed determining that inasmuch as the Committee of the British Medical Association had, in their appointment of readers of addresses, ignored the claims of the profession in Brighton, it was not expedient for the medical men of that town to take any official part in the annual meeting of the Association to be held in Brighton in August. On Tuesday a special meeting of the Committee of the Council of the Association was held at the office in London for the purpose of considering this resolution. The matter was discussed at length, and it was proposed to appoint a sub-committee to confer with the Brighton practitioners as to the best means of ensuring a successful meeting there. To that an amendment was submitted to the effect that the annual meeting in August be held at Brighton, and expressing a hope that the medical men there would cordially co-operate in furthering its objects. In the result the amendment was carried, and the decision was ordered to be communicated to the members of the profession in Brighton.

Medical Education of Women.

IT is clear that those who are in favour of the medical education of women do not intend to let the matter drop. In the present number we report the reception by the Lord President of the Privy Council of a deputation from the Governors of the London School of Medicine for Women. The object of the deputation was to ascertain the intention of the Government with reference to the question of the registration of women as qualified to practise medicine. It was explained in the speeches that there is no law prohibiting the admission of women to the medical profession, and that in the Act of 1858 the word male does not once occur. Lord Aberdare, the late Lord President of the Privy Council under the Liberal Government, assured the Duke of Richmond that strong support would not be wanting from the opposite side of the House should the Government take action upon the question, and suggested that the true way of meeting the difficulty would be

to require the nineteen examining bodies to examine candidates without distinction of person. From Mr. Stansfeld's speech we learn that women require to be placed on an equality as regards examination and registration, and funds will not be wanting to supply them with hospital instruction and other requirements. The Duke, in reply, said he quite saw the force of the arguments put forward, and promised his best attention to the subject, but he could not at present announce a distinct line of action.

George Green Gascoyen.

On Wednesday last a meeting of the staff and the students of St. Mary's Hospital was held to consider the question of founding a memorial to the late Mr. George Gascoyen. Mr. Spencer Smith, who occupied the chair, briefly reviewed his life as a student successful in the prize examinations, as House Surgeon, Curator of the Museum, Registrar, Demonstrator, and afterwards Lecturer on Anatomy, Surgeon and joint Lecturer on Surgery, and Dean of the Medical School. Mr. Smith, together with Mr. Samuel Lane, Mr. James Lane, Dr. Broadbent, and Mr. Woodman, referred in terms of affection to his truthfulness and to his devotion to duty, to his amiability as a colleague, and to the quiet and unostentatious manner in which he had effected real and hard work. A committee was formed consisting of the staff of some of the past and of the present students, and a subscription list was at once opened. It will be left to the committee to decide what form the memorial shall assume.

London Hospital Sunday.

The treasurers and governors of all hospitals and dispensaries within the metropolitan area who desire that their institutions shall participate in this year's distribution have been requested to send in their applications to the Secretary before the 8th day of March. A copy of the last published report, with the accounts and balance-sheet of each institution for the past year, must accompany all applications to participate, otherwise no notice will be taken of the application.

The Dwellings of the Poor and Post-mortem Examinations.

Some time ago we referred to the holding of wakes in houses in which several families resided. Last week a medical practitioner received a notice to make a post-mortem examination upon the body of a woman who had died suddenly. This woman had resided with her husband and two daughters in a back kitchen. The dead body was kept in the same room, and after the wake the family slept and took their food whilst the corpse was still there Fortunately the cause of death proved to be syncope ; but had it been an infectious disease probably the arrangements of the family would not have been altered. The guardians of the workhouse had refused to allow post-mortem examinations to be made at the workhouse, except on bodies found in the street ; after some difficulty, however, sanction was obtained to perform the post-mortem in the case referred to at the workhouse.

The above is only a solitary instance among the many which prove the necessity of increasing the number of public mortuaries and post-mortem rooms.

Telegrams have been received announcing the appearance of the plague on the banks of the Euphrates.

In the House of Commons, on Thursday last, Sir Michael Beach obtained leave to introduce a Bill to amend the law relating to cattle disease.

Dr. A. B. Shepherd will lecture on the Natural History of Pulmonary Consumption at the Royal College of Physicians of London on March 10, 15, and 17.

The Skinners' Company have given 250 guineas towards the fund now being raised for the new Grocers' Company's wing of the London Hospital.

On Thursday last, at Banbury, ten men were fined 30s. each for refusing to vaccinate their children. The men and a number of their friends were driven round the town in vehicles drawn by three horses.

The selection of a gentleman to fill the Professorship of Midwifery in the Queen's College, Galway, is postponed until the 1st of September next, up to which date applications will be received from candidates.

On Thursday last, at a meeting of the Bolton Infirmary, two donations of £5,000 each were announced. One was from Messrs. Musgrave, ironfounders ; the name of the other donor was not disclosed. The donations are towards the erection of a new infirmary which is to be built.

Mr. R. A. Milner, Chairman of the Keighley Board of Guardians, has been summoned before the magistrates of that town for refusing to vaccinate his children. The bench allowed a fortnight's time for compliance with the law, the defendant protesting he would never have his children vaccinated.

The Medical Society of the College of Physicians, Ireland, will meet this day (Wednesday) in the College Hall, Kildare Street, at 8 p.m. The following business is on the paper :—

1. Adjourned discussion on Dr. Hayden's paper on "Biliary Colic."
2. Dr. Grimshaw: "A Case of Abdominal Aneurism resulting in Recovery."
3. Mr. E. Lapper, F.C.S. : "On the Antiseptic Power of Salicylic Acid and certain of its Compounds compared with other Antiseptics therapeutically considered."

Rejections at the College of Physicians.

A copy of the following extract from the Report of the Examiners for the Licence of the College of Physicians of London has been sent to the medical schools :—

"The examiners feel it to be their duty to inform the College that candidates for its licence present themselves for the pass examination very imperfectly prepared, as a rule, on the subject of chemistry in its applications to pharmacy, pathology, and toxicology ; and some have been rejected on account of their ignorance of this subject whose attainments in other respects were satisfactory.

"The examiners venture to suggest that the College

might with advantage take some step to make generally known to students at the several medical schools the imperative necessity for candidates for the College licence, in order to avoid disgrace and disappointment, to present themselves as well prepared on the subject of chemistry in its applications to pharmacy, pathology, and toxicology, as on the other subjects of the pass examination."

We may remark that the examining bodies have hitherto been so lax in their examination upon chemistry that we are not surprised that students almost altogether avoid its study. Ridiculously short is the extent of time which the student allots to this subject. He knows that he will require only a very superficial knowledge of chemistry to pass either the College of Physicians, the Hall, or the College of Surgeons, and the result is, that unless he is preparing for the University of London, he neglects the subject *in toto* until within a few days of the examination, when he contents himself with but little more than a general idea of the atmosphere, water, the gases, and one or two of the more important metals.

The examining bodies alone are answerable for the gross ignorance of the subject of chemisty displayed by the majority who enter medical practice in the present day. We have repeatedly called attention to the fact, and though the College of Physicians has the credit of being the first to take up the matter, we feel bound to add that it is to be regretted that it has been allowed to rest so long unheeded.

Literature.

THE CHARACTER AND LOGICAL METHOD OF POLITICAL ECONOMY. (a)

This is the second edition of Professor Cairnes' Lectures on Political Economy delivered some years ago in the Dublin University. In this edition numerous passages have been recast, and that increased prominence has been given to aspects of the subject only touched on in the former edition, and some entirely new topics have been introduced. He disclaims all pretence to the enunciation of any *new* method of conducting economic inquiries, contenting himself with bringing back the discussion of political economy to those tests and standards which he considers have been completely lost sight of in many modern publications. He at once avows his object to be to state clearly the character of the science as it appears to have been conceived by that succession of writers of which Adam Smith, Malthus, Ricardo, and J. S. Mill are the most distinguished names.

In his introductory chapter Professor Cairnes attacks those writers who enrol themselves as political economists, not because they have made a serious study of the subject, but merely to qualify them to seek popular favour; and he contrasts the vulgar superficiality of those new pretenders with the severe and logical style which characterised the cultivators of the science in the early part of the century. He shows that the most modern views have been constantly assuming more of a statistical character, that results are appealed to instead of principles, and that *statistics*—the mere collection and classification of numerical results—are superseding the canons of inductive reasoning, and that so the true purpose of the science has been well-nigh forgotten.

The author takes for granted that "wealth," the subject-matter of political economy, is susceptible of scientific treatment, that there *are* laws of its production and distribution, that mankind, in their industrial operations, are *not* governed by caprice and accident only, but by motives which act extensively and constantly, which may, therefore, be discovered and classified, and made to serve as the principles of subsequent deductions. He also takes for granted that a knowledge of these laws is a useful study, well fitting to be part of a liberal education, independently of its practical utility; and he considers this knowledge far more likely to be obtained by systematic inquiry than by trusting to what is called the *common sense* of practical men, which he terms "the crude guesses of unmethodised experience."

Professor Cairnes gives an eloquent exposition of what he considers political economy to be. He says: " . . . Political economy is a science in the same sense in which astronomy, dynamics, chemistry, physiology are sciences. The subject-matter is different: it deals with the phenomena of wealth, while they deal with the phenomena of the physical universe; but its methods, its aims, the character of its conclusions are the same as theirs. What astronomy does for the phenomena of the heavenly bodies; what dynamics does for the phenomena of motion; what chemistry does for the phenomena of chemical combination; what physiology does for the phenomena of the functions of organic life;—that political economy does for the phenomena of wealth—it expounds the laws, according to which these phenomena coexist with or succeed each other—that is to say, it expounds the laws of the phenomena of wealth. . . . If you ask me wherein lies the utility of such an exposition, I answer, in precisely the same circumstance which constitutes the utility of all scientific knowledge. It teaches us the conditions of our power in relation to the facts of economic existence, the means by which, in the domain of material well-being, to attain our ends. It is by such knowledge that man becomes the minister and interpreter of Nature, and learns to control Nature by obeying her."

The lectures abound in fine passages of this kind, in which our author developes an enthusiasm without which teaching must necessarily be the dreariest of commonplace. That he was a master of his subject, and had bright and happy modes of attracting the attention of his pupils thereon, has been well attested by many of them. The volume must be looked upon as a popular exposition of political economy; as such it has few rivals, and none in which greater clearness of apprehension is displayed. Many will read it who would turn aside from Mill's didactic and elaborate treatise, fearing to encounter his massive collection of facts and inferences; the one is a fluent lucid *résumé*, while the other is the cyclopædia of the science. There is no suggestion of rivalry. Professor Cairnes would have been the last to think his book in any measure a substitute for Mill's great work. His object was to present the subject in an attractive form; this he has done admirably.

(a) "The Character and Logical Method of Political Economy." By J. E. Cairnes, LL.D., Emeritus Professor of Political Economy in University College. London: Macmillan. New York: Harper.

Correspondence.

THE HASTINGS WATER SUPPLY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The divergence of statement between "M.D." and myself, and the variance of opinion, are so wide, that I could not hope to satisfy either "M.D." or yourself on these in the space which I could reasonably expect to occupy. I shall venture to ask insertion to replies to only two or three points brought forward in your last number.

The most important of "M.D.'s" statements is that concerning the assumed deficiency of quantity in the water. The figures quoted are undoubtedly found in Mr. Topley's report; so also is there a table (p. 8) showing the "mean annual daily flow" to be 254,525 gallons, which is rather less than half the quantity which "M.D." quoted. It would be logical sequence to calculate that quantity at seven gallons per head, and to assume it to be the whole supply to the borough. Mr. Topley also quotes figures (p. 3) showing 741,000 gallons per day supplied during the year 1869, and on page 8 that the "maximum daily flow," in 1874, into Old Roar reservoir *alone* was 614,800 gallons. What becomes of the differences in quantity now stated? It is used to strengthen the weak link in the chain which "M.D." hangs up for exposure. The Town Council possess storage space for 70,000,000 gallons of

water, and this is reserved for use in periods of mean daily flow. Every one of those store places are filled during maximum flow. Those who desire to get at truth only may feel that I have disposed of one highly important discrepancy between us.

The "constant service" question is the next point at which we are at direct issue. "M.D.'s" assertion, "their mouthpieces have of late told us positively that the expense is too great," would be accurate with the qualification, "on the high levels." Hence my "guarded" expression, "a partial trial." My assertion would have been more accurate by the omission of "nor water enough" in the sentence "there is neither pumping power nor water enough to do so." Water is now actually running to waste from the reservoirs, and in certain portions of the low levels it has been "on" day and night—which I suppose to be "constant service"—for some time. From Fairlight alone, at the present moment, the town is receiving 253,000 gallons per day. This may be as mystifying to "M.D." as the statement that £41,000 has been borrowed or asked for; but both are true.

The grounds for charges against the Council respecting the water are about as strong as those which induced the attack on the magistrates in the columns of the *Daily Telegraph*.

I will not trust myself to mention any of the other points introduced in the letter of "M.D.," or the article on the subject in your last. Cogent and sufficient answers can be furnished, but I shall not attempt it in your pages.

Yours faithfully,

Feb. 25, 1876. J. COGSWELL.

HASTINGS WATER SUPPLY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Mr. Cogswell has already published in a local paper a letter, a duplicate of which he states that he has sent to you, I am enabled to place my reply by its side.

The table on page 8 of Mr. Topley's report, referred to by Mr. Cogswell, gives the mean annual daily flow in 1874 of the *springs and streams only*—it does not include the *wells*, which supply more than 300,000 gallons per diem. It would not, therefore, be "logical sequence," but absurdly fallacious, to "assume that 254,525 gallons a day represent the *whole* supply to the borough."

Mr. Cogswell then goes on to say that 741,000 gallons a day were supplied during the year 1869.

We have nothing here to do with 1869. As I said in my former letter, we must test a water source by *unfavourable* years in order to discover its real value. I will, however, state, parenthetically, that even that quantity, including the additional sources of supply since that time, is 300,000 gallons too little.

When Mr. Cogswell tells us that the *maximum* daily flow into Old Roar reservoir in 1874 was 614,800 gallons, he overlooks the fact, stated in my letter, that Mr. Topley condemns 88,351 gallons as surface-water of an objectionable kind. These 88,351 gallons were furnished as follows:—

Old Roar reservoir	62,141	Mean daily flow in 1874.
No. 1 ,,	26,210	
No. 2 ,,		
	88,351	

Of course Mr. Cogswell cannot intend that I should deduct the *maximum* flow of Old Roar from the average daily supply of the year. That would give us rather less than nothing for our water supply. But neither can he mean that it should be stored for future use; for I must again remind him the water of Old Roar is thrice condemned in Mr. Topley's report, and *should not be used at all*.

Nevertheless, *storage* appears to be Mr. Cogswell's only argument.

Now the fact that after a rainy season there should be a phethora of water running to waste, while at other times scarcity amounts to famine, only shows how dependent we are upon *surface-water*. It is chiefly surface-water which is stored in our reservoirs, and to point out that the water of this borough *will not bear storage*, I quote from Mr. Topley's report, p. 8—9, the following extracts:—"The reservoirs of the Hastings Water-works are uncovered, and are constructed with sloping sides. With these arrangements the water cannot continue pure when stored, even if it be of tolerable purity when first admitted into the reservoirs."

"The water *stored* in the Hastings reservoirs is mainly the surface drainage of more or less cultivated land."

"It is proposed to construct reservoirs in the Fairlight and Warren valleys. It is probable that the water of these streams, although of fair quality for immediate use, cannot safely be stored in open reservoirs for any length of time."

I must not encroach further on your valuable space, but I have stated enough to indicate Mr. Topley's opinion on storage of Hastings water.

Mr. Cogswell affirms his belief that my statement about the wells here is a fiction. I can only say that I am prepared with indubitable evidence to maintain the truth of all that I have written.

I remain, Sir,

Your obedient servant,

M.D.

St. Leonard's Club, March 3, 1876.

ON THE ORIGIN OF SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to your remark on the above subject, although it seems doubtful whether it existed in Europe before 1493, may it not have been in other countries centuries previous to that date? Without having any wish to magnify the failings of the great Psalmist, I must say it has often forcibly struck me on reading the Bible version of the thirty-eighth Psalm, that it is a very good description by David, as if he was suffering from the disease. Any attempt to spiritualise away those plain expressions would not satisfy my mind. I am not aware if there is any record of the Israelites having suffered from the disease, but it has been supposed circumcision was ordained as a prophylactic. This would only help to prove there is "nothing new under the sun."

Yours truly,

GREGORY SALE, L.R.C.S.I., &c.

P.S.—As I have not a copy of the Septuagint at hand, I am not aware what is the original Greek word, as the word translated loins may be indifferently translated groin, reins, testicles, &c., *kenεon*, for example.

ABSENCE OF VAGINA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—A young woman who was married for some years came here a few days ago requesting surgical aid, as she never could perfectly cohabit. On making a very careful examination I found the vagina was absent; she had in place of it a sack or hollow inside the external parts about one inch deep, with the urethra very wide, from constant attempts to force a finger into it in the usual situation, but otherwise quite natural. On passing my finger into this passage, through which I drew off her urine, and through which she menstuated, I found the neck of the uterus unusually long, presenting its usual feel, and in every particular, otherwise than its length, natural, coming from the posterior superior wall of the bladder. She is a healthy woman, but always menstruated rather scantily, and rather later than natural. This unusual malformation I wish to notice, as I have never met a like one.

Yours faithfully,

VERNON WM. RUSSELL,

Surgeon County Tipperary Infirmary.

The Infirmary, Cashel, Feb. 21, 1876.

CAPILLARY BRONCHITIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following case of modified capillary bronchitis, which has been described by Dr. Parrish, of Philadelphia, may be interesting to your readers:—

Charles C——, aged one year and eight months had recovered from measles a fortnight ago.

On the night of February 12 I was sent for in a great hurry, and on arriving found the child in a collapsed state.

The eyelids were half-closed, the eyeballs turned up, the lips bloodless, the cheeks deadly cold, while the other parts of the body were warm; the skin moist and soft; the countenance had an anxious expression; the tongue was covered with a white thick fur; the bowels regular. He breathed with a peculiar grunt at the end of each expiration. There was a short dry cough, great difficulty in breathing, muco-crepitant râles at inspiration and expiration heard from apex to base of both lungs. T. 103, R. 72, P. 172.

I prescribed—

℞ Ol. tereb., ℥xvi.;
Mucil. tragac., ʒiv.;
Antim. tart., gr. i.;
Infus senegæ, ad ʒij.

A teaspoonful every ten minutes. A teaspoonful of punch every fifteen minutes. Poultices of linseed back and front of the lungs.

After taking about eight doses of the bottle, he vomited up a great quantity of white frothy mucus. I now omitted the antimonum tartaratum.

Feb. 13th.—The child had brightened up; the lips were a better colour; the grunting at the end of expiration had ceased; but there was still difficulty in breathing; the cheeks had lost their deadly coldness, but a profuse perspiration had broken out over the whole head, saturating the pillow; there was no perspiration from the rest of the body. T. 102, R. 72, P. 172.

I took an ounce of blood by wet cupping over the first bone of the sternum. Treatment as before.

14th.—The perspiration from the head still continuing; breathing with a wheezing sound, but much easier. The palms of the hands and soles of the feet have become quite livid in appearance. T. 100·4, R. 72, P. 148. Ordered the bottle to be given only every third hour, and the punch every hour. Flying blisters to the front of both lungs,

The child continued to improve in every way. The perspiration from the head had ceased; the difficulty of breathing had disappeared; the cough had become quite soft; the temperature had fallen to normal, and the respiration and pulse nearly so, when diarrhœa set in on the 16th, which carried him off on the night of the 19th, in spite of every remedy that was tried. A few hours before death the cheeks became deadly cold again, the rest of the body being normal heat.

MARTIN O'CARROLL,
66 Amiens Street, Dublin. Lic. Med. Univ. Dub.

Obituary.

JOHN MORGAN, F.R.C.S.I.,

Professor of Anatomy in the Royal College of Surgeons in Ireland.

No death within the profession in Dublin—even in Ireland—has produced so profound a sensation as that of Professor Morgan; no event has, for several years, so deeply agitated or shocked the personal feelings of his brethren in Dublin as this most melancholy occurrence. No loss to the profession will be felt throughout Ireland to come nearer to the hearts of each of our readers than the removal of John Morgan under the solemn circumstances which have attended it. But two days before the news of his untimely death he had been seen actively engaged in his practice, and had met his brethren in those terms of friendship and of genial intercourse which marked his relations to them through his professional life; and almost as soon as the rumour that he had been stricken down in illness had reached them came the tidings of his desperate state, and close upon it the shocking tidings that he was no more. Even the stranger, who knew him only by repute and by the affectionate mention of his name, the violence and suddenness of the blow brought solemn thoughts; to those who had been his associates and friends it brought deep grief and unavailing recollections of his genial qualities, now extinguished by the inflexible hand of Death. These feelings of distress and of affectionate regret were intensified by the recollection that the poor fellow himself had suffered but recently the anguish of domestic bereavement, which had overwhelmed him under exactly similar circumstances of painful suddenness, and from the shock of which his spirit had but imperfectly recovered itself. For three days before his death Professor Morgan had suffered from a *malaise* which he felt himself to be peculiar in its nature, and which had caused him to be indisposed for active business, but which, nevertheless, did not prevent his attending to his hospitals, his College duties, and his private practice, or meeting his friends without any obvious change in his spirits, his manner, or his appearance. On Thursday evening he showed signs of being seriously ill, and on Friday morning was so alarmingly worse that all the resources of medicine were called to his help—alas! without effect—for steadily and rapidly, and almost without rally, he sank and died of rapid enteric fever on Saturday, at 2.30 p.m.

Professor Morgan was the second son of Thomas Morgan, Esq., of the Bank of Ireland, his mother being the elder sister of Dr. Arthur Jacob, and he was born in the year 1829. His early education was obtained in Dublin, and after his academic career in Trinity College, during which, with the independence so characteristic of the man, he acted as a classical teacher, Mr. Morgan obtained the Arts Degree in 1849, and in the following year became a Licentiate of the Royal College of Surgeons. He was at once appointed a demonstrator of anatomy in the School of the College, and under the auspices of his uncle, Arthur Jacob, entered into active professional life as an anatomical teacher, joined first by Dr. Malcolmson (now of Cavan) and then by Dr. Mapother, with whom he formed classes for private instruction, which, as regards numbers, have never been approached in the Dublin or perhaps any other Medical School. During the years of the Crimean War we are informed that these classes consisted of over two hundred pupils annually; and the energy and talent which he applied to their education bore its natural result, not only in the remarkable successes in life of those who had studied beneath his rostrum, but in the life-long respect and friendship of those who had profited by his exertions. In 1861, the late John Hatch Power having been transferred from the Anatomy to the Surgery Chair in the Royal College of Surgeons, Dr. Morgan was unanimously elected thereto, and there never was a more popular lecturer. His facility of expression, energy, and great accuracy were indeed remarkable; the most intricate subject being treated most fully without a note or any other aid to memory. Like his uncle, Prof. Jacob, he was devoted to the pursuit of mcoparative anatomy, and for three years in the College of Science delivered courses upon that subject which delighted both scientific and popular audiences.

Previous to this time he had been chosen Surgeon to the Adelaide Hospital, where he had acquired his first character as a skilful and well-judging surgeon, which he afterwards confirmed in his connection with Mercer's, and which secured for him the Surgeoncy of the Lock Hospital, and placed him in a position to command the honours of the profession. At the early age at which he has been removed from his professional sphere of life he had achieved such a position in his own College that he might with every probability of success have claimed its Presidency, and, it may be said without offence to the many eminent and competent men amongst his colleagues, was *facile princeps* in the School of the College. While so busily engaged in special surgical work, he had not been indifferent to the claims of his less fortunateiy situated brethren, and he devoted himself with characteristic vigour to the working of the Irish Medical Association, in the management of which he was one of the most earnest and most judicious actors, and in the future of which he evinced a more firm belief and a greater zeal than very many who profited by his exertions.

Professor Morgan's attainments as an anatomist and teacher are but household words in Ireland, which need no

repetition in these pages. His robust and lucid style, his fluency of speech, his clearness of illustration, and his joviality of manner will recur to the mind of many of those who read these words, and who have listened with admiration to his lectures. He knew his subject—felt it a pleasure to elucidate it, and possessed a remarkable power of expressing himself, and was altogether a teacher amongst a thousand, and by a geniality which was consistent with professorial dignity he endeared himself to his pupils not only as an instructor, but as a friend. As a surgeon, Professor Morgan was bold, yet judicious, and all his contributions to the literature of the profession bore a stamp of originality and close observation. His connection with the Lock Hospital (in the Surgeoncy of which he succeeded Dr. Thomas Byrne about six years since) caused him to adopt the treatment of venereal disease as one of his specialities. He held strong views as to the unity of syphilitic virus, and in his work, "Practical Lessons on the Treatment of Contagious Diseases," he gave expression to his opinion, and brought a strong force of experimental evidence to confirm it. He had been the first to disinter the valuable inoculation experiments of Mr. Wallace, which had remained for many years unused in the archives of the College of Surgeons, and at the time of his death, being engaged on a second edition of his work, he had but a few weeks since made a journey to Spike Island for the purpose of obtaining information from the convict Kirwan in reference to certain illustrations of syphilitic disease which had been executed by him for Mr. Wallace.

His labours in the investigation of anæsthetics are well known, and he is entitled to the credit of having reintroduced the use of ether to Irish surgery. By the inhaler which bears his name he placed at the disposal of the profession the only really satisfactory means of administering that anæsthetic, and by the influence of his writings and example he succeeded in great measure in banishing chloroform from a place in Irish surgery. His numerous contributions to the Surgical Society of Ireland and his paper on the "Immediate Treatment of Contracted Joints by Extension" marked him as a surgeon of judgment and of large experience, which, no less than his suave and jovial manner, was rapidly obtaining for him the public confidence.

The critic whose task it is to review the professional life and personal qualities of John Morgan finds it an easy task to keep his eulogium within the limit of severe truth; it would be well for the good name of the profession if—when the obituary of each of us comes to be written—as much that is approving and as little that is censorious could be set down.

Scanning the career of John Morgan within the profession, or his personal characteristics without it, there will scarcely be found a fault which would be worthy to be inscribed upon his life history, while his qualities as a surgeon and a friend will not cease to overshadow those foibles from which none of us are free.

In the memories of the present generation of Irish surgeons none but feelings of affectionate regard will be recalled by the regretful mention of his name.

JAMES WARBURTON BEGBIE, M.D.

James Warburton Begbie was the second son of Dr. James Begbie, long well known and highly esteemed as a consulting physician in Edinburgh. He was born in 1826, and being from boyhood destined to follow his father's profession, he was educated at Edinburgh University and Surgeon's Hall, and afterwards studied in the Continental schools of Paris, Vienna, and Italy. He obtained the degree of M.D. in 1847, and was elected a Fellow of the Royal College of Physicians in 1852. In 1855 he was appointed a physician and clinical lecturer in the Royal Infirmary; and about the same time he began to lecture on the practice of medicine in the Extra-Academical School. In the session of 1856-7, he delivered at Surgeon's Hall an extra course of lectures on the "History of Medicine," a series which was continued through several subsequent summer sessions. Dr. Begbie was appointed Examiner in Medicine for the Edinburgh University, in succession to Dr. Sellar, in 1869; but he had only acted in that capacity for about a year when the pressure of other engagements obliged him to resign the office.

On the death of his father, which occurred in 1870, his engagements as a consultant became so numerous that he abandoned all ordinary practice, his services being called for not only in Edinburgh and throughout Scotland, but even in many parts of England.

In August last, in recognition of his professional eminence, Dr. Begbie received from his Alma Mater the degree of LL.D., and in the same month he delivered the address on the ancient and modern practice of medicine at the meeting of the British Medical Association. Dr. Begbie was second to none in the thorough knowledge he had of his profession, and in the unsparing pains and devotion with which he applied himself to its study. His contributions to literature were very numerous, most of them in the form of papers in the *Edinburgh Medical Journal*. His articles on "Diseases of the Liver," and "Diseases of the Nerves," in "Reynolds' System of Medicine" are well known.

He was an excellent classical scholar and an accomplished modern linguist, an able and attractive lecturer. As a clinical teacher he was distinguished, and by his impressive manner and desire to instruct, he gained the esteem and confidence of every pupil who attended his wards.

His considerate and amiable demeanour and the interest he took in those who consulted him gained for him an unusually large circle of friends. It is not then surprising that his practice became unusually large, and it is believed that his health was impaired by the overwork entailed upon him by his professional position. He had suffered for some years at times from weakness of the action of the heart, but only lately had he determined to take some rest. On the 7th ult. he left Edinburgh with the intention of proceeding to Italy, but the symptoms increasing, he found himself unable to travel beyond Carlisle, and he consequently returned home.

The symptoms of nervous exhaustion now gradually increased, and though suffering no pain, dyspnœa became a source of trouble to him. He was suffering from the effects of an enlarged heart with fatty degeneration, as proved afterwards by post-mortem examination. He was conscious throughout, but sank gradually, and died at two p.m. on Friday the 25th ult.

DR. CUTHBERT OF DERRY.

We have pain in recording the death from typhus fever on the 1st of March of Dr. Alexander Cuthbert, of Derry, a surgeon of considerable culture and much esteemed in his county. Dr. Cuthbert was comparatively young in his profession, having received his qualification in 1856. In 1860 he was appointed to the Glendermot District of the Londonderry Union and afterwards became House-Surgeon to the Derry Infirmary, under the late Dr. Babington. Finally he succeeded to the Londonderry Workhouse and Fever Hospital in the year 1873, which he held up to his death. He was the author of several papers of note—one on "Prominent Features of Ulster Revival," published in the *Medical Times* in 1859; and another on "Paralysis caused by Working under Compressed Air," published conjointly with the late Dr. Babington in 1866. He has fallen a victim to the conscientious discharge of his duty, and his sad end has evoked much sympathy.

Medical News.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,936 births and 4,129 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 27 deaths annually in every 1000 persons living. The annual death-rate was 25 per 1000 in Edinburgh, 25 in London, 31 in Glasgow, and 37 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 21, Hull 20, Leicester 17, Sunderland 11, Portsmouth 20, Newcastle-upon-Tyne 22, Birmingham 24, Brighton 22, Leeds 27, Wolverhampton 28, Bradford 29, Sheffield 25, Plymouth 20, Bristol 23, Oldham 25, Manchester 36, Salford 32, Nottingham 26, and Liverpool 36. The annual death-rate from the seven principal zymotic diseases averaged 3·7 per 1000 in these towns, and ranged from 1·4. and 1·5 in Wolverhampton and Newcastle-upon-Tyne, to 6·5 and 7·9 in Sheffield and Liverpool. Small-pox caused 9 more deaths in Manchester and Salford. Measles and whooping-cough are fatally prevalent in Liverpool. The fatal cases of fever in Sheffield were 11, against 7 in each of the two previous weeks; 249 deaths have been referred to fever in this borough since the end of July last. In London, the 1,691 deaths included 2 from small-pox, 44 from measles, 47 from scarlet fever, 2 from diphtheria, 88 from whooping-cough, 15 from different forms of fever, and 17 from diarrhœa; thus to the seven principal diseases of the zymotic class 215 deaths were referred, a lower number than in any week since the end of May last. These 215 deaths were 34 below the corrected average number from the same diseases in the corresponding week of the last ten years.

The Queen at the London Hospital.—Yesterday (Tuesday) was a grand gala in East London. For several days past the local authorities and the public on the route through which her Majesty would pass to open the new "Grocers' Wing" have been busily engaged in decoration, and when Tuesday dawned with truly magnificent weather, all hearts were glad. Indeed her Majesty must have been highly gratified with her reception as she passed under the triumphal arches, and with the words of welcome from myriads of Stentorian throats and the tastefully devised and well chosen mottoes on all sides. Even the historic "Aldgate pump" was clothed in velvet and gold in honour of the occasion, whilst the trophy at the entrance of the hospital surmounted with the words. "I was sick and ye visited me," formed a most appropriate and impressive welcome as she entered that vast building she had come to declare open for the good of humanity. Owing to our being compelled to go to press before the ceremony was concluded, we must defer details for our next. Suffice it to say that the arrangements were in harmony with the beauty of the morning, and reflected the greatest credit upon all concerned.

Cloth Tents.

Dr. C. Henri Leonard, of Detroit, Michigan, writes to the *Chicago Medical Journal*:—

I have been using, quite extensively, in my gynecological practice, a tent that I have made out of cloth. It has proven of so much service to me that I have thought it might be of value to give it to the profession.

Some time ago I had occasion to make Emmet's operation upon a conoid cervix, for the relief of dysmenorrhœa and sterility, and I made use of them for intra-cervical packing; that is, to keep the cut edges of the cervical canal from uniting. At the first application they were very readily introduced (a sponge-tent having previously been used), and seemed to be just the thing. On the next day's visit, the neck having contracted somewhat, I was completely foiled in their introduction, and so had to resort to lint plugging. It at once struck me that if a *wire* could be introduced, in some way, *into* the cloth cone (Hippocrates had stiffened them by wrapping them around with horse-hair), their objectionable feature would be entirely removed.

On my return to the office, I tried rolling a piece of hair wire into the cone, and found that it answered exactly. Since then I have made use of them for almost all purposes as a dressing-applicator to the uterine cavity. They are equally applicable for dressing any other sinus-like canal, whether from wounds or otherwise.

To make one, you need but a strip of linen six inches in length, by three-fourths of an inch in width, a piece of hair wire four inches long and a few inches of common thread. Roll one corner of the linen strip lightly between the thumb and finger, then unroll and place the centre of the wire at the corner so rolled, and then roll the cloth at this corner over it (*spirally*, just as you would go to work to make a paper lamp-lighter), till you get *almost* to the other corner of the same end, then bend the wire upon itself (double it, in other words), so that the two extremities will point to the unwound portion of the linen; this done, continue rolling the linen, in a *spiral* manner, about the double wire till exhausted, then tie with the thread the last spiral turn about the wire. You now have a tent about two and a-half inches in length, and one sufficiently firm to enter *any* normal uterine canal, and most any abnormal one. You can bend it to any curve you choose, to facilitate its introduction. It has still another advantage over all other tents, in that you can leave it *in sitû* (as I frequently do for twenty-four hours), with *no* danger to your patient, as it is inexpansible, and hence no excitor of metritis, though a stimulator (from its very slight mechanical irritation) to the endometrium. By so doing you can get a *prolonged* action of a medicament upon the lining membrane of the uterus, which is impossible to get by any other method of application. Further, you need not use such energetic local applications, and you may be sure that they reach the *whole* uterine cavity; something you cannot do with our intra-uterine applicators, unless you are a very skilful manipulator. The shape of the fundus-cavity is an anatomical proof of the great difficulty of making a complete application with the common metal applicators; whereas the czoth tent, by meeting with resistance at the fundus, immediately doubles upon itself, thus occupying the whole cavity.

You cac make them of any *size*, and of any degree of stiffness, by increasing the thickness of cloth, and the size, or number of doublings, of your wire. I have them of all sizes, from those suitable for an ante-puberic uterus, to one as large as your index finger.

I use them now for cleansing the uterine tract previous to an application of astringents or other medicaments thereto, and find they clean away the tenacious mucus much better than a syringe or a wisp of cotton on Emmet's applicator. Indeed, it is invaluable in many ways. By leaving the thread without the vulva, the patient can as easily and safely remove it at her residence, as can her physician. You have only to remember to tie a string (or a coloured thread) to the cotton pledget you leave in the vagina, so that she may be made aware which to remove (pull) first.

Taking all these points into consideration, with their plea of cheapness and cleanliness (to the operator, for they are thrown away as fast as used, and need be touched only with the tip of the dressing forceps), I am sure they will commend themselves to any one who will take the trouble to make up a half-dozen for trial.

Detection of Arsenic.

M. Armand Gautier recommends a new method for the destruction of organic matter in searching for arsenic in the animal fluids and tissues, by means of which he has certainly obtained most excellent results. His method is as follows.

About one hundred grammes of the tissues are cut up, placed in an evaporating dish, thirty grammes of concentrated nitric acid added, and the whole warmed gently. It is not necessary to divide the organs into such small fragments as when the other processes are used. The heat should be withdrawn when the mass becomes viscous and tends to attach itself to the sides of the vessel. Then add six grammes of concentrated sulphuric acid, and heat moderately till the brownish-black mass begins to adhere to the bottom of the dish. Next add, drop by drop, fifteen grammes of nitric acid, continuing the heat just to the point of vaporising the sulphuric acid. The whole liquefies, and nitrous fumes are evolved. Continue the heat till the mass begins to carbonize, and dense fumes are given off. The black residue is then easily reduced to powder and extracted with boiling water. Filter, reduce the filtrate by boiling with the acid sulphide of sodium, and precipitate the arsenic with sulphuretted hydrogen in the ordinary way.

The advantages of this method are that no arsenic is volatilised as the terchloride, that the carbonaceous mass left upon the filter paper contains no arsenic, and that all the arsenic originally present can be isolated and estimated.—*Boston Medical and Surgical Journal.*

VACANCIES CREATED BY THE DEATH OF DR. MORGAN.

By the lamented death of Professor Morgan many valuable appointments in the Irish surgical profession are opened to competition. The Professorship of Anatomy in the Royal College of Surgeons, which he held conjointly with Dr. Bevan is worth about £350 or £400 a year, according to the number of the class. The selection of his successor is in the hands of seven of the Council of the College, who shall (according to Charter) be selected by lot for the purpose, and, in the ordinary course of events, the appointment would be made within a fortnight or three weeks. It is possible, however, that, as the Anatomical Lecture Session is approaching its termination, the Council may defer their choice of a successor until the advent of the next winter's teaching. His office of Surgeon to Mercer's Hospital will be filled by the medical staff of the hospital, while his appointment in connection with the Lock Hospital is in the hands of the Lord-Lieutenant, under recommendation from the Board of Governors.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Notice to Subscribers.—The Publishers will be glad to receive the subscriptions for the past year, 1875—£1 2s. 6d. Subscriptions in advance for 1876, at the reduced tariff of 21s. per annum, post free, must be paid before the end of this month in London, Dublin, or Edinburgh.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

"Another Dispensary Doctor."—Your letter was omitted through want of space, but will appear in our next Supplement.

Royal College of Surgeons of England.—On Wednesday and Friday, at 4 p.m., Prof. W. K. Parker will lecture "On the Shoulder-girdle and Fore-limb of Vertebrata."

Medical Society of London.—This evening, at 7 p.m., Dinner of the 103rd Anniversary.

Obstetrical Society of London.—This evening, at 8 p.m, Presentation of Models, &c., with Remarks by Dr. Arthur Farre. Mr. Jonathan Hutchinson, "On the Importance of Studying the Diseases incidental to Parturition in the Lower Animals, with especial reference to those in the Sheep." Dr. John Williams, "On the Mechanical Action of Pessaries." Dr. Cooper Rose, "A Contribution to the Statistics of Midwifery in General Practice."

Dr. A. B. Shepherd will deliver the Gulstonian Lectures at the Royal College of Physicians of London on March 10, 15, and 17 at 5 o'clock. Members of the profession will be admitted on presentation of their cards.

Epidemiological Society.—This evening, at 8 p.m., Dr. W. E. Smart, "On the Cholera Epidemic of 1873 in the Basin of the Mississippi, chiefly with relation to its Importation in Fomites."

Clinical Society of London.—On Friday evening, at 8½ p.m., Mr. Maunder, "On a Successful Case of Gastro-enterotomy (Artificial Anus in the Small Intestine) in a Male aged 68" (the Patient will be present). Dr. Greenhow, "Aneurism of the Arch of the Aorta spontaneously Cured, with Obstruction of the Left Carotid and Subclavian Arteries." Mr. Holmes, "On a Case of Distal Ligature of the Left Carotid Artery for Aortic Aneurism"; "On a Case illustrating the Utility of Linhart's Chisel in Excisions."

How to Dine.—We have received A Family Dinner Carte from the publishers, Messrs. Cassell, Petter, and Galpin, which is intended to be hung on the wall deemed most suitable for every-day reference. The compilers of this chart have taken the pains to think for those to whom the question of "how shall we dine?" is a source of anxiety and annoyance, and have arranged each day's repast, mindful both of economy and of the changes of viands which each season of the year necessarily entails. To housewives with moderate pecuniary allowances for the weekly fare this chart will doubtless be found useful.

Society for Relief of Widows and Orphans of Medical Men.—A quarterly court of this Society will be held on the 12th proximo for the election of candidates to participate in the funds at the disposal of the committee. Forms of application can be had at the Society's offices.

Dr. B. T. B., Paris.—We do not know the book you mention, and cannot therefore give you any idea of its chances of acceptance in this country. If you will send a copy we will look through it.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Diseases of the Eye. Third Edition. By C. Macnamara, F.C.U. London: J. and A. Churchill.

Lectures on Surgery. Vols. I. II. By James Spence, F.R.S.E. Edinburgh: A. and C. Black.

Outline Drawings for Recording Cases of Skin Disease. By Balmanno Squire, M.D.

A Dictionary of Hygiene and Public Health. By A. W. Blyth, M.R.C.S. London: Chas. Griffin and Co.

The Non-Alcoholic Treatment of Disease. London: Baillière, Tindall, and Cox.

The Student's Guide to Dental Surgery. By Hy. Sewill, M.R.C.S. London: J. and A. Churchill.

Helmick's List of Counterfeits.

The Practitioner. The Veterinary Journal. The Obstetrical Journal. New York Medical Record. Canada Lancet. Melbourne Medical Record. The Clinic. Philadelphia Medical Times. Le Progrès Médical. Allgemeine Wiener Medizinische Zeitung. Boston Medical Journal. Students' Journal, &c., &c.

VACANCIES.

Queen's University.—Examinerships in Medicine, Surgery, Midwifery, Materia Medica, and Jurisprudence. For the value of each and other particulars see Advt.

Manchester Royal Infirmary.—Hon. Assistant Surgeon. Particulars of election of the Secretary.

Kent County Lunatic Asylum.—First Assistant Medical Officer. Salary, £220, with furnished apartments, &c. Address the Clerk to the Visitors, Maidstone.

Nottingham Dispensary.—Assistant Resident Surgeon. Salary, £100. Applications, with testimonials, to the Committee at the Dispensary.

Lisnaskea Union.—Medical Officer Brookeborough Dispensary District. Salary, £115, with £15 extra as Sanitary Officer.

Hospital for Diseases of the Throat, London.—Physician. Honorary. Applications to the Secretary, Golden Square, W.

Infirmary for Consumption, Margaret Street, London.—Physician. Honorary. Applications to the Secretary.

Carlisle Dispensary.—Assistant House Surgeon. Salary, £90, with apartments. Address Mr. Davidson, 8 Devonshire Street.

South Devon Hospital.—House Surgeon. Salary, £80, with board. Testimonials to the House Surgeon, Plymouth.

APPOINTMENTS.

Davis, H., M.R.C.S.E., L.S.A.L., Resident Medical Officer to the Lewes Dispensary and Infirmary.

Dunlop, W. M., Medical Officer to the Suffolk Provident Dispensary.

Eyedey, J. F., L.R.C.P.L., M.R.C.S.E., Medical Officer for the No. 1 or Northern District of the Plymouth Incorporation of the Poor.

Farquharson, P. D., M.B., C.M. Univ. Aberd., Medical Officer for the Parish of Applecross, Ross and Cromarty.

Fox, J. M., M.R.C.S.E., L.S.A.L., Medical Officer of Health for the Workington Urban Sanitary District.

Herman, G. E., M.R.C.P.L., F.R.C.S.E., Medical Registrar to the London Hospital.

Hyde, G. E., L.R.C.P.L., M.R.C.S.E., a Surgeon to the General Infirmary, Worcester.

Maybury, W. A., M.D.Q.U.I., M.R.C.S.E., Medical Officer for No. 1 Ward District of the Colchester Union.

Morgan, W., Ph.D., Public Analyst for Carmarthen.

Parker, R. W., M.R.C.S., Surgical Registrar to the London Hospital.

Purcell, R., L.A.H.D., Apothecary to the Workhouse and Croom Dispensary District of the Croom Union, co. Limerick.

Reed, J., M.R.C.S.E., L.S.A.L., Medical Officer for No. 2 District of the Westbourne Union, Sussex.

Marriages.

Freeland—Gilkinson.—On the 23th ult., at Glenhuntly, Port Glasgow, John Ellis Freeland, M.D.C.M., to Margaret, fourth daughter of the late David Gilkinson, Esq., of Glenhuntly.

Deaths.

Damant.—On the 23rd Feb., at Fakenham, Thomas W. Damant, M.D., aged 56.

Dyce.—On the 1st March, Thomas Rose Dyce, M.R.C.S.Eng., Deputy Inspector-General of Hospitals, aged 59.

Jolliffe.—On the 25th Feb., at 16 Godolphin Road, Shepherd's Bush, John Jolliffe, M.R.C.S.Eng., aged 61.

Lewis.—On the 23rd Feb., at 6a St. Mary's Terrace, Maida Hill, Alfred Lewis, M.D., Surgeon, Army, aged 34.

Marshall.—On the 29th Feb., at Padiham, John Marshall, M.D., aged 31.

Newsam.—On the 16th Feb., at Pembroke, Thomas Henry Newsam, L.R.C.P.Ed., aged 48.

O'Sullivan.—On the 21st Feb., at 56 Rupert Street, Haymarket, London, Robert Collis O'Sullivan, M.R.C.S.E., aged 58.

Pettinger.—On the 27th Feb., George Pettinger, M.D., Manchester, aged 73.

Smith.—On the 2nd Feb., at Loftus-in-Cleveland, James Broom Smith, M.D., M.C., and L.R.C.P.Ed., aged 35.

ON TUBERCULOSIS IN CHILDREN AND THE CONDITIONS WHICH RESEMBLE IT.

By W. H. DAY, M.D., M.R.C.P.Lond.,

Physician to the Samaritan Hospital for Women and Children.

BY the term tuberculosis we mean a general condition of ill-health, associated with the deposition of tubercle in one or more organs of the body: it is a constitutional febrile affection which usually succeeds inflammatory action in the lungs, bronchial glands, cerebral meninges, and peritoneum. In childhood it has some special and characteristic symptoms which we do not observe in later life, and the causes and history have a separate and distinct character. In well marked cases of tuberculosis the children are usually good looking, with prominent veins, long eyelashes, and dilated pupils; the figure is erect and slim, the joints are small and slender, and the shafts of the bone thin and straight; the growth of mind and body is active, and the nervous system is highly impressible; the child is sensitive to reproof or kindness, quick and clever at his lessons, and he does not exhibit the backwardness which belongs to the phlegmatic temperament. These children are not subject to enlargement of the lymphatic glands, nor have they the thick lips and dull expression of the truly scrofulous diathesis. Tuberculosis, then, or the tuberculous cachexia, signifies that state of constitution which arises from the presence of tubercles, and by tubercles is meant a species of new matter, or growth, prone to degeneration and decay. In its crude condition it resembles concrete albumen, and consequently becomes soft and friable, and acquires the consistence and appearance of thick cream, or cheese, or pus. But a variety of circumstances will determine the character of the exudation, and it may abound in elements at one time which are not to be detected in it at another. It is a non-plastic serous exudation, derived from the liquor sanguinis of the blood, which is poured out upon the surface of the mucous membrane of the air cells, or deposited within the parenchymatous structure of the lungs, where, instead of being absorbed or excreted, as happens in the simple exudative inflammations of the healthy, it slowly degenerates by reason of its inherent faulty composition and deficient vitality. Tubercles, which may be the result of the inflammatory process when the blood is wanting in nutritive materials, may possibly be independent of inflammation, and exist as the consequence of morbid action, possessing no resemblance to the healthy tissues in which they are found. They are the local expression of a depraved constitutional state, and are most likely, in many instances, the products of a low scrofulous degeneration. When few in number they occasionally become hard and indurated, and do not interfere with the patient's daily habits; but when they are numerous they affect the general health, and if deposited in the lungs, cause in most instances an alteration in the physical signs, and lead to softening and suppuration of the tissues in which they are deposited. Under the microscope irregular bodies (tubercle corpuscles) are seen, having an oval or triangular form, and in their longest diameter, vary from the 1-2000th to the 1-1200th of an inch, according to Hughes Bennett.

Tubercular exudation is most commonly met with in children and young persons who have reached adult age. It occurs in the lymphatic glands, the lungs, and serous membranes, and its progress is generally slow and insidious; but, on the other hand, it is sometimes rapidly roused from latency into activity, or set up anew by some common-place disorder. There is no attempt at absorption, or perfect cell formation, but a tendency to ulceration and disintegration with a certain train of general sym-

ptoms, recognised by failing health and strength, and persistent derangement of the digestive functions.

According to Virchow, although tubercle is a result of the death of healthy or diseased tissues, the local process —tuberculosis—also results in the exudation of a material during tuberculous inflammation; such material undergoing a kind of organisation, succeeded by its death, and by its breaking and shrivelling up into a tubercle. This gradual change is termed tuberculisation. (*a*) There is much evidence to be adduced in support of that theory which classifies tubercle as a primary formation like cancer and epithelial and melanotic growths. All the changes that take place are secondary, and without the presence of malnutrition it seems highly probable that no lesion can produce it. (*b*)

The conditions, then, under which tuberculosis originates are not precisely known, as low inflammatory products may cause induration or suppuration, and yet the disease may not be developed. It is not known whether the disease is specific or not, or how it is generated within the body. When the sputa of phthisical patients have been given to dogs and poultry, tuberculosis has sprung up; and the same has been the case with cattle fed with tubercular or scrofulous products. Villemin was the first to show, by a series of experiments, that when finely divided masses of grey or yellow tubercle were introduced under the skin of guinea pigs, rabbits, and some other animals, a local form of inflammation ensued, and at the end of two or three weeks miliary tubercles were discovered in the lungs, and at a later period in the intestines and peritoneum. Villemin therefore concluded that it was possible to propagate tuberculosis by inoculation in the same way that occurs with small-pox and syphilis. Many pathologists have carried out Villemin's experiments, and they have arrived at precisely the same results, whilst Burdon Sanderson and Wilson Fox made the further discovery that miliary granulations arose in some of the chief organs of the body when pus, putrid tissue, and portions of a pneumonic lung were introduced subcutaneously. Dr. Burdon Sanderson's (*c*) experiments on the artificial production of tubercle in the lower animals diffuses much light on the pathology of the affection as it occurs in man. He found that it is most readily produced in the guinea-pig, next in the rabbit, and lastly in the dog. "For three reasons," says Dr. Sanderson, "the guinea-pig is preferable: (1) because it is absolutely free from liability to natural tubercle; (2) because it is little liable to acute inflammation; and (3) because it can be inoculated with absolute certainty." An infinitesimal dose of the infective material is taken from the diseased gland of an infected animal, and after being mixed with a little distilled water, is injected into the peritoneum, the pleura, or subcutaneous areolar tissue. Drs. Sanderson and Wilson Fox, in 1868, produced tuberculosis in the guinea pig by the insertion of setons and non-tubercular products. An abscess followed around the foreign body, and tuberculosis supervened. Professor Cohnheim also confirmed these experiments, and produced tuberculosis traumatically, by introducing harmless foreign bodies into the peritoneum. The result obtained by these researches was to produce nodules of new growth, having a lymphatic structure, and termed lymphomas by Virchow, because they are commonly found in certain organs of the lymphatic system. Dr. Sanderson proposes the term adenoid, because he says in certain parts of the body there are organs like these growths we are considering which possess a structure identical with the follicles of the lymphatic glands, and that where they exist naturally, as beneath the pleura and peritoneum, there these tubercular nodules or overgrowths are most frequently found. These nodules or tubercles appear in fact to be nothing more than overgrown masses of pre-existing tissue, or enlarged anedoid bodies. (*a*)

In fact, these pathologists ascertained that simple mechanical irritation set up the same morbid processes as the inoculation of the specific products I have alluded to. Thus it seems satisfactorily demonstrated that general tuberculosis may arise from the inoculation of a morbid poison into a wound, or from the absorption of inflammatory products; and although the injection of tubercular matter does appear to induce the disease with greater certainty and celerity, there is no reason whatever to suppose that any specific inoculation is necessary. These carefully conducted experiments have had a surprising effect in modifying our views regarding the prevailing doctrine of tubercle, and as we shall subsequently see, they have an important practical bearing. It decides the long disputed question that low forms of simple or even acute inflammation in some subjects may eventuate in tubercular disease, without any original deposition of tubercle; and in support of this view, I may allude to the circumstance that neglected pleuritic effusion in children is occasionally followed by empyema and tuberculosis. A common cold in delicate children, or those predisposed to the affection, will now and then give rise to it; no vascular excitement in such subjects is to be disregarded.

The exact nature of tubercle has led to much controversy and difference of opinion. Mr. Gulliver describes grey tubercle to consist of cells, and yellow tubercle of degenerating cells, granular matter and oily particles. He regarded tubercle as a low form of organisation, and Dr. Addison entertained a similar view. Rokitansky was of opinion that tubercles consisted of nucleated cells of various sizes, and to be an exudation of altered fibrin from the vessels—miliary tubercle to be a fibrinous variety of lymph, and yellow tubercle to be a croupous or corpuscular variety. Niemeyer considers that tubercle has very little to do with the production of phthisis. Dr. Beale defines tubercle to consist of living matter, and like pus and cancer possesses the power of growth and multiplication; (*b*) but he considers it impossible to distinguish the living matter of tubercle from the living mass of pus and cancer.

The grey and yellow varieties are the kinds with which we are familiar. The grey granulations are composed of minute red cells, about the size of a white blood corpuscle, and with a nucleus smaller than a red corpuscle, separated by a delicate reticular network, except where they are densely massed together. The reticulum is the germinal matter of Dr. Beale.

It may be stated that, for the last 200 years, tubercles were considered to be allied to scrofulous lymphatic glands till the time of Bayle, who regarded turbercle as a peculiar product, and the result of a special constitutional diathesis—a deposit depending on a morbid state of the blood. Bayle gave the name of tubercle to the grey and yellow masses which he found in the lungs. The *grey tubercle* of Laennec and Bayle has been considered pneumonic by most persons; the *yellow* and *caseous* tubercle was only a transformation of the grey. Virchow proved that yellow caseous matter was not the character of true tubercle, and that it might arise from fatty degeneration, and the products of pus, and cancer, and so forth. He

(*c*) "Recent Researches on Artificial Tuberculosis." *Edinburgh Medical Journal*, November 1869.

(*a*) I am quite willing to acknowledge a close affinity between lymphatic glandular swellings and tubercles, for they affect the same subjects and run a similar course. But these glandular swellings also have a close resemblance on the one hand to swellings from inflammation, and on the other to the simple enlargement of the spleen and liver occurring in lucæmia. In both these cases there is doubtless hypertrophy or hyperplasia, but this may be in the way of exudation or cell proliferation, without the development of complex tissue which constitutes a *growth*. If the addition of cells, fibres, and other products of inflammation in a tissue, constitutes a growth, then common cutaneous pimples, tubercles, and boils, are growths, and the swelling from erysipelas or cellulitis must be included under the same term; but this surely would exceed its usual acceptation.—"Pulmonary Consumption," by D. Williams, p. 17.

(*b*) "Trans. Path. Soc.," 1873. Vol. xxv., p. 316.

called the *grey* granulation of Bayle the typical form of tubercle, and considered infiltrated tubercle and caseous masses as the consequence of inflammation. Dr Wilson Fox takes the view that the caseous products arising in the lung in phthisis are due to the destruction of vessels by a new growth in the walls of the air vesicles, and that the typical grey granulation is not the only form in which tubercle occurs.(*a*) Niemeyer, as I have before stated, considers that phthisis as a disease has nothing to do with tubercle, which is only an accidental and secondary product when found in the lung, and the result of inspissation of inflammatory products, leading to destructive and ulcerative changes in the lung tissue.

Dr. Fox's researches seem to show that the changes found in the lungs, in acute tuberculosis in children, are the same as those observed in the ordinary forms of phthisis; but there are certainly some anatomical characters which distinguish the disease in early life.

According to this authority, (*b*) the following are the chief appearances found in the lungs of children dying of acute tuberculosis:—"The semi-transparent granulation of Bayle. Opaque white granulations, for the most part soft, but with varying degrees of firmness and difficulty of crushing. Granulations like the semi-transparent granulations of Bayle, and also like the soft granulations, but more or less caseous in their centres. Yellow soft granulations, easily crushed, but not easily removed from the pulmonary tissue, varying in size from that of a poppy seed to a mustard seed, rarely of the size of a hemp seed, and still more rarely of the size of a split pea. Caseous granulations, dry, opaque, and friable: sometimes with, sometimes without, a grey transparent zone of induration surrounding them. Groups of granulations, mostly like the semi opaque, sometimss entirely opaque, rarely semi-transparent; two, or three, or four, or more in number, reaching the size of a split pea, or a bean, or even a small walnut, or hazel nut. Indurated pigmented granulations, singly or in groups like the last described. And lastly, tracts of indefinite extent, one or two or more inches in diameter, irregular in outline, prominent above the surface, granular on section or tearing of the tissue, but passing sometimes insensibly into the so-called grey infiltration. Cavities, from infinitesimal specks to the size of a hazel nut or larger. Granulations softening into cavities—either the softer—the white or the yellow. The semi-transparent granulation is not, as far as I have seen in the lung, found softening into a cavity without some intermediate change. Tracts of grey semi-transparent appearance, known as the "grey pneumonia" or "gelatinous pneumonia," or "grey infiltration" or gelatinous infiltration of Laennec; spots also of red pneumonia; in some cases œdema; in some cases injection or punctiform extravasation; in some cases emphysema and collapse; in some cases capillary bronchitis and dilatation of bronchi. The point on which I wish especially to insist, is that the grey granulation of Bayle is very seldom found alone. They are sometimes found as isolated structures scattered throughout the whole lung, but this is comparately rare. In the combinations of eleven cases they were only found alone in two. They either co-existed with caseous, or with the white and the soft, or with the caseous, or with the soft and caseous, or with the indurated, or with the soft, yellow, and caseous, or with the soft and caseous alone; most of these being combined either with red or grey pneumonia, or with tracts of caseous infiltration. Those are the forms of the combinations of which I made notes in eleven cases that died under my own observation. The grey granulation of Bayle, the typical tubercle of Virchow, does not therefore exist alone in the majority of cases of acute tuberculosis in the lungs of children. It is most commonly associated with other granulations, which have a different appearance to the naked eye, and also a different anatomical structure; and the latter, in some cases, are the predominant change, so that in some lungs the grey granulation is comparatively rare."

Unlike the case of adults, grey granulations and crude miliary granulations frequently exist in children as the only form of tubercular deposit. In the adult M. Louis discovered miliary tubercles alone in 2 out of 123 cases (1·6 per cent.), and grey granulations alone only in 5 more (4 per cent). In the child Rilliet and Barthez found miliary tubercles without grey granulations in 107 cases out of 265 cases, and grey granulations alone in 36 out of the same number of cases. In 102 cases of phthisis in children, Dr. West (*a*) found miliary tubercles alone in the lungs in 20 instances, and grey granulations alone in 17 more. Another anatomical peculiarity in early life is the great frequency of yellow infiltrated tubercle. It seldom exists alone, but is generally associated with crude yellow tubercle and grey granulations, and sometimes with advanced disease of the bronchical glands. Rilliet and Barthez met with it in 88 out of 265 children, or in 33 per cent. of their cases.

THROMBOSIS—ILLUSTRATED BY CASES. (*b*)

By W. I. Wheeler, F.R.C.S.,

Member of Council, Surgeon to the City of Dublin Hospital, Licentiate of the Royal College of Physicians, M.D. Trinity College, Dublin, &c.

The subject which I have the honour to bring under the notice of this Society, namely, Thrombosis, or the coagulation of blood in vessels, being full of interest, and having been described by earlier and even recent writers under different nomenclature, as phlebitis, pyæmia, &c., I purpose giving a brief outline of the views of some of the authors on this subject.

Artæus was the first, as far as I can ascertain, who attempted any description of venous inflammation, but with such inaccuracy and vagueness that to John Hunter is generally attributed the credit of describing inflammation of the lining membranes of veins. Ambrose Paré says, sometimes in the limbs they contain a thrombus of blood dry and hard, which the vein being opened should be evacuated. Petit writes of clots in veins and also of changes they suffer. Due attention was, however, paid at this period to wounds of veins and to clots within their channels, with varices and obstruction. Michel and Frank, after Hunter, have described inflammation of the inner coats of veins, and from thence phlebits appears to have been divided into adhesive and suppurative.

Gardien ("Histoire Anatomique des Inflammations") "finds the inner coat of an inflamed vein of a red colour, and on separating the inner from the middle coat the injected capillaries became more distinct, even in the structure connecting the inner with the middle coat. Afterwards the inner coat becomes uniformly red, and is less transparent, so that vessels beneath are no longer distinguishable; it loses its polish and becomes somewhat rough. If the disease advances it becomes swollen, and has a villous appearance, and could be readily detached from the middle coat but for its tearing so easily. The latter or middle coat quickly thickens, so that the vessel resembles an artery, but not so resisting. The external coat is infiltrated with blood. A membrane sometimes lines the vessel, of little consistence, forming a cheesy pulp when pressed between the fingers." Ribes has observed this membrane to be firm and resisting and organised, although slightly adherent to the adjacent wall. The blood now forms on the walls of the vessel fibrinous clots, by which the tube becomes blocked up. The clots are not formed immediately, but "fresh fibrinous layers

(*a*) "Diseases of Infancy and Childhood." 4th Edition. 1859. P. 448.

(*b*) Read before the Surgical Society of Ireland, Friday, February 18, 1876. The discussion will be found at p. 220.

are being added, and in a short time a plug is formed, which fills the entire of the vein." This fibrinous coagulum extends above and below, beyond the limits of the portion inflamed The plug by degrees ceasing to be made up of concentric "layers, gradually passes into a tapering coagulum," more or less tinged with the colour of the blood, and little if at all adherent. In all the branches of veins which immediately lead to the plugged portion, save those which have other channels, the blood stagnates and coagulates. The plug seldom extends beyond the point of junction with the nearest venous trunk. Such is the description of changes stated to take place in adhesive inflammation of veins; or, as it is summed up by Mr. Callender in his excellent paper on this subject in "Holmes' System of Surgery," that their inner and middle-coats become inflamed, lymph is exuded and clings to the surface next the blood; the latter coagulates, and so the vein is filled partly with lymph and partly with clots. Then, as in every other inflammation, the mingled products undergo further changes. There is a difficulty (as expressed by Mr. Callender) in receiving such statements in the face of facts which throw doubt upon the existence of an adhesive phlebitis. Every pathologist is aware how quickly after death veins become stained, and occasionally the adjacent tissues. Ribes, in writing on inflammatory action in the radicals of the vena portæ of persons dying of adynamic fever, calls attention to this. Guthrie, in his treatise on gun-shot wounds, doubts that adhesive inflammation of veins exists, being entirely at variance with Gardien. Frank saw differently, and observed "a sort of false membrane, resulting from the inflammatory action." Cruveilhier did not regard phlebitis as the first change, but considered coagulation anterior to it. Nor did he observe on the lining membrane of veins vascularity, even when the blood, charged with irritants from the inflamed part, caused inflammation. Hunter (*a*) did not understand how adhesions could take place on the inner surface of veins, when it was plain that the lymph thrown out on the internal surface of the vein, mingling with the same fluid circulating with the other parts of the blood, would be carried away without producing any effect; but that since adhesions do happen, the coagulable lymph must undergo some change connected with the disposition which produces its extravasation.

According to Callender, Travers was the first to show that veins after ligature or division repair without adhesive inflammation; and preparations at St. Thomas's and St. George's Hospitals verify this fact. And from the experiments made by Callender and others there is no doubt that the lining membrane of these vessels does not inflame when irritated. Obvious it is, from the very contradictory statements, that adhesive phlebitis has been very differently described, and not admitted by some pathologists.

Before passing on from the term phlebitis, I cannot help alluding to the interesting papers written by the late Dr. Robert Mayne, Physician to the Adelaide Hospital, on Adhesive Phlebitis in connection with Chronic Dysentery, published in the *Dublin Pathological Reports;* also a case of adhesive phlebitis after parturition, by Dr. M'Clintock, which he associates with pyæmia, published in the *Dublin Quarterly Journal* of 1856.

The drawings illustrating these cases have been most kindly lent to me by Mr. B. W. Richardson, Surgeon to the Adelaide Hospital.

Both these cases are remarkable, showing phlebitis of the venæ innominatæ. I may here state I have met one case of phlebitis with dysentery occurring in the person of Gunner Michael King, Royal Artillery, who died at Zoola Camp during the Abyssinian campaign. The right axillary and the basilic veins were plugged; the veins of the forearm were much enlarged.

The term thrombosis, or thromballosis, under which term Mr. Callender treats of adhesive phlebitis, I understand to mean a coagulation of the blood during life; and thrombus, the coagulum within the vessel, occurring most commonly in veins. I shall merely draw attention to the fact—as it is unnecessary for me here to do more—that ante-mortem and post-mortem thrombi are vastly different; and I will briefly mention some of the causes of thrombosis and its result thrombus:—

Stoppage or extreme slowness of the current;
Contact with an abnormal surface;
Increase of fibrine in the blood;
Pressure on the vessel.

Such are some of the more common causes of thrombosis; and when a thrombus is formed it is liable to undergo changes of various kinds. It may become organised; it may disintegrate, or pass away; the exterior of the clot may harden and unite with the thickened wall of the vessel, and the centre of the clot soften and open up as a channel (described by Mr. Gay); or, after some time, both the clot and the vessel may dwindle away, and become a fibrous cord; or the coagulum may soften into a puriform fluid, turbulent with white corpuscles. But this puriform matter, accepted as purulent, was denied by Goodsir and his followers, as from microscopical observation it was believed that this puriform matter was molecular detritus, and not pus. This assertion was adhered to for a long period, till it had to be admitted that the non-purulent character of this puriform matter was not conclusive. Virchow states a large quantity of pus-like corpuscles are present in this puriform matter, but these corpuscles have been attributed to the fact that red cells are much more easily destroyed than white, and that when red corpuscles have disappeared, being dissolved or washed out, the white remain, having the appearance of pus cells, and although there may be such a number of pus cells as to make this appear impossible. Rindfleish accounts for it by saying, that the adhesive property of the white cells permits them to cling to the surface of the clot, or to permeate its substance, and fresh layers of clot form over such white cells; and thus he thinks this explanatory how such a large number of pus-like cells can be present.

Cohnheim's experiments on the inflamed mesentery and cornea of a frog show that the pus is out-wandering white blood cells; and Weber has got the white blood cells to take up cinnabar, a clot first being formed, and found these cinnabar-bearing cells in the clot.

Thus suppuration, founded on Cohnheim's experiments, makes it hard to discern between the pus-like cell bearing matter in such clots from pus.

Dr. Duval, however, denies the accuracy of Cohnheim's theory, as, from his experiments on the cornea, he has arrived at the conclusion that the pus corpuscles appearing in severe inflammation of that membrane are caused by the proliferation of the plasmatic cellules of the corneal tissue, and not from the white corpuscles.

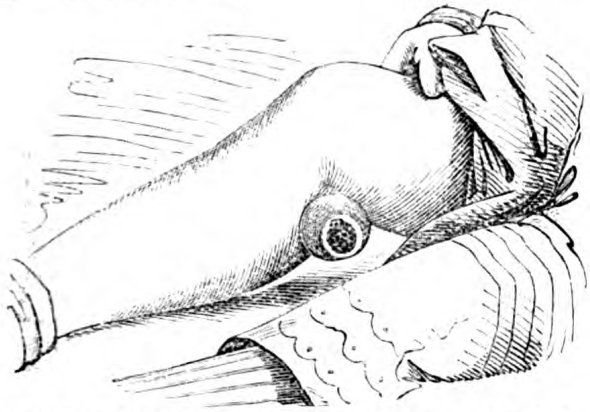
I shall now proceed to give a description of a case which came under my care in the City of Dublin Hospital, recommended by my friend Dr. Charles Lyster, of Kilkenny, one of the Fellows of this College.

Mary M., æt. 27 years, residing at Kilkenny, married, the mother of four children, all healthy, and she herself apparently in the enjoyment of good health, was admitted into the City of Dublin Hospital on the 6th of August, 1874, for a tumour on the right leg. The history of the case, as given by the patient, taken most carefully by my former pupil, Mr. Keighley Marks, now a Member of this College, is as follows:—About four months previous to her last confinement, and seven to her admission, she first noticed two kernels swollen under the back of her right knee. This swelling afterwards moved to the side of her leg, a little below the bend of the knee-joint, the site of the present tumour being at the commencement about the size of a marble, and increasing within the last three months till it had attained its present size. In the centre of the tumour was a small opening where it had burst a week previous to admission, through which there was a slight discharge of purulent matter of a reddish tinge. The tumour was firm circumferentially; there was not any

(*a*) Hunter's Works, vol. iii.

œdema of the limb, nor had there ever been. She never suffered pain. No thickening or enlargement of the saphenous vein existed inferiorly, but for about one inch above the tumour there was some slight thickening.

The drawing present, done by Mr. Thomsohn, then artist at Messrs. Forster's, shows most truthfully the appearance of the tumour.



I removed the tumour on August 22, 1874, and brought the parts together by means of two hare-lip pins. The patient recovered, and was discharged on the 8th Sept., 1874. There was not any deformity, there merely being a fine seam designating where union had taken place between the lips of the wound.

I now, Mr. President, hand you the tumour—a beautiful specimen of fibrinous thrombus of the saphenous vein, in which softening took place, pus-cells were present, the innermost coat absent in some portions of the channel now holding the clot, which I have cut into to show better its laminated appearance; the other coats of the vein were much thickened, and the vessels enlarged and distended. With regard to the formation of this thrombus, I believe it to be due to an altered condition of blood, hyperfibrinization and perchance tension of the vessels, both conditions common in pregnancy. With regard to the softening of the clot, it has taken place at the centre, as is evident not only from the drawing but the specimen; and with respect to the pus-like cells, which were in quantity found on microscopic examination, the enlargement of the vessels supplying the other coats of the veins would lead me to the conclusion that there was a transudation or out-wandering of the white cells from these distended vessels to the clot, and probably also an entanglement of others from the blood forming the thrombus, as Rindfleisch states may occur.

As thrombosis, phlebitis, and pyæmia have been and are still held to be closely associated, I had intended to conclude this communication by discussing their relations; but time will not permit. I would therefore refer those who desire information to Mr. Savory's able paper on the subject in the second volume of St. Bartholomew's Hospital Reports for the year 1866, in which he shows that neither thrombosis nor phlebitis stands in any especial or peculiar manner to pyæmia as cause and effect.

In conclusion, I will merely add that the treatment which appears to be indicated in cases of thrombosis is to keep up the patient's health by tonic treatment and a generous diet. Rest must be insisted on, and the circulation established in the superficial veins. If there be pain from inflammation, it can be soothed by warm fomentations and opium. Mercury and blistering are contraindicated. In the gouty form of thrombosis described by Sir James Paget, a diminution of food and stimulants, with fomentations to allay pain, seems to be the treatment he relies most on. With regard to a case similar to that which I brought before the Society this evening, I would adopt the same line of treatment, or did a case like it present itself to me without having burst, it would occur to me that the same practice might be the most judicious.

CASE OF CARDIAC DISEASE, WITH EMBOLISM, CEREBRAL SOFTENING, AND APHASIA.

By John Hawtrey Benson, F.K.Q.C.P.,
Physician to the City of Dublin Hospital.

The specimen was taken from the body of a girl æt. 20, who died in the City of Dublin Hospital. Three years before she had rheumatic fever, during which she contracted mitral valve disease, and afterwards great hypertrophy of heart. She had been since then a patient in the house several times on account of this double disease. On the morning of the 8th of August, 1875, she was discovered to be suffering from complete right hemiplegia, and the cause ascribed at the time was embolism of left middle cerebral artery. Well-marked aphasia next followed, and on the 12th of October she had an epileptiform seizure. The characteristic collapsing pulse of aortic patency was well marked, and equally so in both radials, till the 15th of November, when the pulse in the right radial artery was found to be weak, and scarcely perceptible, while the left pulse was unchanged. Of this the cause ascribed at the moment was "embolism of some portion of the artery leading to the wrist." On tracing the artery upwards a spot was soon found (situated precisely where the axillary artery changes its name into brachial) above which the pulsation was strong and collapsing, and below which it was weak and scarcely perceptible. A sharply defined line of demarcation thus indicated the position of the embolus.

Post-mortem Examination.—The heart greatly hypertrophied; aortic valves extremely diseased, with numberless vegetations and extensive disintegration. The left middle cerebral artery was tightly plugged with a hard knot-like embolus. For half an-inch beyond the seat of the embolus the artery presented a contracted, silvery, cord-like appearance, without any trace of blood in its interior, but where the artery bifurcated each branch was seen to contain blood, showing that a certain amount of circulation by anastomosis was permitted in those branches.

The greater part of the left side of the brain was atrophied more or less, and had undergone advanced white softening. These conditions were well marked in the corpus striatum, optic thalamus, hippocampus major, hippocampus minor, left side of pons varolii, and posterior portion of anterior lobe, as well as in the general mass of the left hemisphere. An old hæmorrhagic clot occupied a great part of the left hippocampus major, and tænia hippocampi, which Dr. Hawtry Benson thought probably occurred at the time of, and was the cause of, the epileptiform seizure of the 12th of October.

Dr. Hawtrey Benson then exhibited a portion of the artery of the right arm occupied by a large embolus situated in the spot ascertained during life, and already described.

Dr. Hawtrey Benson then drew attention to the unbroken chain of events and consequences extending over a period of three years presented in this case, and to the difficulty of predicting with certainty the result of embolism of any given cerebral artery in any given case. Whether the result would be white softening or extravasation of blood would depend, he considered, on the freedom of the collateral circulation and the degree of degeneration of the arterial system on the one hand, and by the soundness of the same system, and insufficient anastomosis on the other, as well as on the size of the individual artery engaged. The speaker also drew attention to the support afforded by this case to the theories concerning the pathology of aphasia advanced by Broca and Hughlings Jackson.

Clinical Records.

CASES IN PRACTICE.

Reported by John W. Martin, M.D.,
Assistant-Surgeon, Mayfield Factory Dispensary, Portlaw, &c.

Case XIV.—*Pain in the region of the Heart—Area of Heart Dulness enlarged—Friction Murmur—Dyspnœa—Palpitation — History of Rheumatism — Treatment—Health restored.*

M. C., æt. 23 years, unmarried, a domestic servant, a well-

nourished, strong, and healthy-looking girl, presented herself for treatment upon the 5th of December, 1874, complaining of symptoms connected with the heart.

The following is the history of her case :—Previous to her twenty-first year she had always enjoyed good health. About that time *she first felt a pain in the region of the heart*, for which she was unable to assign any special cause. This pain was always worst during the menstrual periods. In the autumn of 1873 she had a slight but decided attack of rheumatism, or at least pain and swelling in several of her joints. The left arm was most affected. For some days before coming under my notice she felt the pain about the heart getting much worse, extending over the whole of the sternal region, and under the left mamma. This increase of pain was accompanied by tenderness to pressure. Any form of exertion, such as stooping, lifting weights, and especially running up stairs, induced very severe dyspnœa and palpitation. She felt greatly inconvenienced after meals, owing to their giving rise to a sense of oppression about the heart. She slept well, lying best on her right side. Area of heart dulness much enlarged ; it extended 4½ inches in the vertical direction, from the upper border of the fourth rib, left side, and from the right border of the sternum, at the articulation of the fifth rib, over towards the left side, to a point two inches external to the nipple line of the left breast. Heart's action excited, accompanied by *frémissement ;* rhythm normal ; impulse weakened and diffused. Normal sounds of the heart very indistinct at the apex, better at the base. First sound distant, prolonged, and roughened ; second sound short, sharp, and accentuated. A well-marked friction murmur heard over the whole surface of the heart, slightly preceding and accompanying the impulse. This murmur was double at the apex. From its superficial character and general diffusion I believed it to be caused by pericardiac friction. I was unable to detect any symptoms of endocardial affection. Pulse 100, weak and compressible. Both lungs healthy. Tongue clean ; appetite good ; bowels regular ; quite regular as to her monthly health. Urine free from albumen or sugar. As treatment I applied a blister over the heart, and ordered—

℞ Potass. iodidi, ʒi. ;
Tr. digitalis, ʒiss. ;
Sp. amm. aromat., ʒij. ;
Syrupi, ʒi. ;
Aquæ ad ʒviij. M.

Two tablespoonfuls to be taken three times a day.

Dec. 13th.—Blister gave immediate relief. The mixture was taken steadily since her first visit. Patient much improved. Pain almost gone. Heart's action stronger and steadier. Area of dulness diminished by one-third. The character of the friction murmur unchanged Able to run up and down stairs with ease, the exertion not being followed by dyspnœa or palpitation. Free from all sense of lassitude, from which she suffered continually when she first came under my care. Treatment continued.

Dec. 19th.—General health and spirits excellent. Free from all pain and distress about the heart. Area of dulness remains somewhat greater than nomal, measuring 2½ inches in diameter. Heart's action and impulse exaggerated. Friction murmur unchanged. Treatment continued.

April 13th.—No change in the state of the heart. General health all that could be desired. Treatment stopped.

April 26th.—A slight return of pain felt in the region of the heart, otherwise feeling very strong and well. Patient thought she had caught fresh cold. Resumed treatment.

The girl having left her situation, and not again coming under my observation, I have no further notes of her case.

The following are some of the points for consideration in connection with the foregoing observations :—

1st. What connection existed between the appearance of the catamenial periods and the exacerbation of the pain in the region of the heart ; the uterine function being apparently quite healthy as regards periodicity, quantity, and quality.

2nd. Is the sub-acute variety of the rheumatic dyscrasia, in which the joints are but lightly affected, the most dangerous as regards affection of the internal organs, such as the heart, &c. ?

With regard to the first of these two points, I can only suppose that the exacerbation was due to the natural constitutional disturbance, which always accompanies the appearance of the menstrual flow. Touching the second, it is a point that has been for some time under my consideration, but as yet I think it is a matter for further observation before attempting to dogmatise upon it. Mr. Hutchinson, in his opening address at the meeting of the Pathological Society, London, upon syphilis, has expressed a similar opinion in connection with the suppression of the external manifestations of that disease, *i.e.*, the less the skin is affected, the greater the danger of the internal organs being so. Gout is another example of a constitutional affection, in which we regard with anxiety the suppression of what may be looked upon as its external manifestations —viz., the pain and swelling in the joints. The case I have noted above is a good example of the heart as the organ primarily affected in one who at a subsequent period was the subject of sub-acute rheumatic affection of the joints ; for such, I think, we have good reason to believe it to have been.

This supposition is supported by the facts that—

1st. The uterine functions were healthy.
2nd. The lungs were equally so.
3rd. No derangement existed of the liver or kidneys, judging by the healthy performance of their functions.
4th. Previous to the affection of the heart she had always been a strong healthy girl.
5th. The seat of disease in this organ was the pericardium, for which, as a serous membrane, the rheumatic poison (so to speak) possesses a special affinity.
6th. Finally, the pain and swelling in the joints, though not acute, were decided.

The strong accentuation of the second sound of the heart in this case is worthy of remark, especially when taken in connection with the permanent enlargement of the area of heart dulness, and the increased force of its action and impulse. In cases of rheumatic dyscrasia, is there increased arterial tension to the extent seemingly indicated by the strong accentuation of the second sound that existed, together with the evident hypertrophy, which in this instance was connected with the left side of the heart ?

In conclusion, I must express my satisfaction with the results of treatment in this case. From a condition of rapidly increasing inability to follow her occupation the patient was restored to a very fair state of health.

Transactions of Societies.

CLINICAL SOCIETY.

A CASE OF MORPHŒA.

Dr. Dyce Duckworth exhibited a male, aged 26, suffering from this disease on the left half of his forehead, which had commenced about four years previously. At that time, it was a smooth slightly-depressed and glossy patch (morphœa plana), of the colour of ivory, and incapable of being pinched up by the finger and thumb. Where it encroached upon the scalp, some of the hairs had fallen out, others had broken off short. No sudoriferous action occurred upon the patch ; and sensibility was blunted, but not lost. The patch continued to grow, and in August, 1873, it was of a darker hue ; some pink vascularity and small venules were visible in places. The greater part of the surface had become raised (morphœa tuberosa); sensibility being greater on the flat than on the raised portions. Some fine downy hairs were growing near the centre of the patch, though there were broken hair stumps at the margins. In March 1875, the patch was less obvious and less raised. Hairs were growing upon it. In February,

1876, the patch was assuming a more natural aspect; no extension had recently occurred; sensation was still blunted; and the patient had a feeling of tightness in the patch. The affected area seemed more vascular and warmer than the adjacent integuments. Dr. Duckworth considered this a typical case of morphœa, and remarked that he had met with no example of the disease existing on the right side of the forehead, though he had collected six cases of the disease on the left side. Local treatment had appeared to be of no avail. Prognosis was favourable, though six or eight years might first elapse. He thought there was no alliance between this affection and true leprosy. Tonics and attention to the general health were the only indicated methods of treatment.

Dr. HILTON FAGGE considered that this disease deserved a special name, for although it resembled scleroderma the latter disease was never localised. If the disease were a fibroid growth in the skin, its interest was enhanced, for atrophy and absorption of a true fibroid tissue is of doubtful occurrence.

BULBAR PARALYSIS.

Dr. DOWSE showed a patient who had recovered under his treatment from bulbar paralysis, the case being the only one recorded in this country which had been completely cured. The patient's history was essentially neurotic. The mother, previously healthy, had died only a fortnight since from an attack of apoplexy of twelve hours' duration. He, when a child about twelve months old, suffered from convulsions, but grew out of them, went to school, and was fairly intelligent. At the age of sixteen, he had a series of well-marked epileptic seizures of great severity, resulting in paralysis of the whole body save those parts supplied by the first, second, third, fourth, and sixth nerves. The paralysis was complete both of motion and sensation. There was trismus of the jaw from palsy of the pterygoids; also of the lips. He could neither bring them together, nor perform the act of whistling. The saliva was constantly making its way from the mouth. The pillars of the fauces and soft palate were immovable. He was fed with fluids, which often returned through the nostrils; and at times he was nearly asphyxiated by its passing into the larynx. Upon admission into the Central London Sick Asylum at the age of twenty, most of the above signs and symptoms were well marked; but the paralysis of the upper extremities was gradually diminishing. He was of stunted growth and dark complexion, and was quite intelligent, though absolutely dumb, and had the greatest difficulty in getting food into the pharynx. His best mode of procedure was that common in such cases, namely, to fill the mouth and with the fingers to push the food over the epiglottis into the bag of the pharynx. The tongue lay flaccid, wrinkled, and immovable, behind the lower row of teeth. Upon ophthalmoscopic examination, the right eye showed cupping of the disc, with enlarged vessels; the left was similar, but the appearances were less marked. The teeth were well defined, and gave no evidence of congenital syphilis. The vocal cords moved freely. The only sound he could make was a sort of grunt. The lower extremities were rigidly extended, and absolutely devoid both of motion and sensation. The heels were well drawn up, as in equino valgus. Dr. Dowse then narrated the progressive return of voluntary power. So far as the bulbar palsy was concerned, it first made itself evident in the motor division of the fifth by movement of the jaw; the lips could then be approximated; the saliva ceased to flow from the mouth; he could feed himself with slowness and some difficulty; but the tongue remained immovable. He continued in this state for nearly twelve months, neither improving nor retrograding. He was taking cod-liver oil, quinine, and phosphorus. The paralysed parts were now brought under the influence of galvanism, and injections of one-sixth of a grain of strychnia and one-twentieth of a grain of atropia were daily used to the lower extremities. At first, the induced current from a two-celled Stohrer's battery was several times applied to the tongue without any result; after this, the continuous current from six cells of Stohrer's battery was then applied, and with the best results, for the tongue was quickly protruded and as sharply retracted. For some days, however, he had no voluntary power over it, but the use of the daily galvanic stimulus shortly ensured this, and articulation soon became perfect. It was for some time almost inaudible, and the letter R was the most inarticulate of all the consonants. With this the power of swallowing soon returned, so that he had complete co-ordinate voluntary power over those parts supplied by the bulbar nerves. The last to regain power and sensation were the lower limbs. The muscular atrophy here was so extreme, that nothing but the tibiæ and integuments appeared left; but the galvanism, frictions, and injections, gave the excellent effects now seen. For, instead of his being a mute, helpless, and emaciated creature, he had complete voluntary power over every part of the body. In reference to the nature of the lesion in the medulla, Dr. Dowse thought that it existed within rather than without this part of the cerebro-spinal system; it might, most probably, be due to venous extravasation during one of the severe epileptic seizures.

Dr. HUGHLINGS JACKSON said that such cases were extremely rare. He had never seen a recovery from bulbar paralysis.

TWO CASES OF LEUKÆMIA—ONE SIMPLE, ONE WITH JAUNDICE, NEITHER WITH NOTABLE ENLARGEMENT OF THE SPLEEN; BOTH TREATED WITH PHOSPHORUS, AND BOTH DYING OF HÆMORRHAGE.

Dr. MOXON read a paper on two cases of leukæmia. The first case was that of a man, a cook, aged 45, who, in December, 1874, fell ill with pain in the right hypochondrium; this was succeeded, in about a month, by jaundice, which remained until his death, in November 1875—the stools, however, always containing bile until the last two weeks. In May, it was noticed that his blood showed an excess of white corpuscles, about 150 in the quarter inch microscopic field. Phosphorus in 1-50 grain doses, as ol. phosp. in mucilage, &c., was taken from May until September, thrice daily. Meantime there was no change in the proportion of white corpuscles. The liver had grown larger, and a double tumour appeared on its lower edge. During the summer and early autumn, the man did half work at his calling, until November 3rd, when he presented himself, severely ill, collapsed, and was admitted again into Guy's, where a peritoneal fremitus developed itself over the liver. He suffered from pain and vomiting, and the jaundice deepened; bile left his motions. He gradually sank then, and died November 16th. Before his death, Mr. Golding Bird examined the blood on the warm stage, and found that the white corpuscles, in great excess as they were, nevertheless all showed amœboid movements, like normal white corpuscles. At the inspection, Dr. Goodhart found a cancerous tumour about the bile-duct at and around its entrance into the duodenum, which obstructed it. The gall-bladder and bile-ducts were immensely distended, and there was a suppurating cyst just outside the gall-bladder, exactly like the cysts found under similar circumstances outside the urinary bladder. A semi-recent hæmorrhage was found to have occurred into the biliary passages, so that a cylinder of blood-clot stopped up the lower end of the dilated bile-duct. The spleen weighed only nineteen ounces. There were hæmorrhagic spots in it, and it showed the usual simply hypertrophic characters of leukæmic spleen. The lymphatic glands were not at all enlarged. Dr. Goodhart found the marrow of the ribs to be loaded with white-blood cell-like corpuscles.—The second case was that of a cheesemonger, aged 38, a pale short man, of boyish appearance, who, in July 1875, began to complain of weakness, which was increased by a shock in a collision of vehicles, in which, however, he did not suffer any bodily injury. His complaint was of languor, loss of appetite, and pains in the loins and testes, "drawing up" the latter. In early September, the blood was found to be loaded with great excess of white corpuscles; and then phosphorus, in 1-60 grain doses in mucilage, &c. (as ol. phosp.), was given thrice daily for a month. During this time the patient grew worse, and at the end of it showed alarming symptoms. The white corpuscles were now estimated at one to every two of the red; vision was dim, and bleeding occurred from the gums, nose, and kidneys. The spleen was just palpable below the ribs; a loud anæmic murmur was heard over the base of the heart. On October 25th he had an attack of apoplexy, of which he died. On inspection, the heart was found healthy; the blood leukæmic. The spleen weighed twelve ounces, and was simply hypertrophied. There was an apoplectic clot of about two ounces weight under the convolutions of the right vertex. Microscopic examination of the tissues showed an excess of white corpuscles in the lymphatic spaces, but the lymphatic glands were not at all enlarged. Dr. Moxon remarked that these cases showed that, when the spleen was not sufficiently enlarged to draw attention, or make a conspicuous feature in a case, and when the lymphatic glands were not at all enlarged leukæmia might be present, and, as in the second case, reach an extreme degree, and prove fatal with hæmorrhage in the usual way. The observation of

excess of white corpuscles in the medulla of the bones was important in reference to Dr. Neumann's supposition that the medulla of bones might be the source of white cells in leukæmia, which source, with the two sources in the spleen and lymphatic glands, made three distinct modes of origin for a disease which was clinically so uniform as to render it very unlikely that it thus varied in its origination. Dr. Moxon referred to the difficulties of circulation in the marrow of the bones on account of the rigidity of the small channels along which the venules passed, and he held that the choking of these venules with white cells in leukæmia would naturally lead to an "out-wandering" of white cells into the marrow of the bones, in the same way as in Cohnheim's experiments, so that the white corpuscles in the marrow were secondary. Again, he went further, and held that, even in the case of the so-called lymphatic leukæmia, the enlargement of the lymphatic glands was really secondary to the leukæmia, and arose by out-wandering of the more numerous white cells, which Mr. Golding Bird had shown to possess amœboid movements, and which passed from the blood into the texture-spaces, in the manner described by Dr. Klein, thus producing lymph-corpuscles in excess, which, going up in the lymph-stream, and reaching the glands, would form tumours there if unable to pass; but, if the glands were able to give passage to them, then there would be no such tumours. In the first case one had the falsely so-called lymphatic leukæmia, in the second, splenic leukæmia. In support of this he mentioned that the cases advanced as lymphatic leukæmia were very few, and in nearly all of these the spleen was described as very large, while in the one or two exceptions either, as in Dr. Hounsell's case, the leukæmia showed only fifteen times the proper number, which is not enough to characterise leukæmia, or else, as in Dr. Ward's case, not only was the proportion of corpuscles doubtful, but the spleen was as large as in the case Dr. Moxon had brought forward, and in which leukæmia was present without any enlargement of the glands. So that this case disposed of the other so far as the glands were concerned. Lastly, as to the phosphorus, it had entirely failed in both cases, and Dr. Moxon remarked that, in the case by Dr. Wilson Fox, the record of which had induced him to try the medicine, the proportion of white cells in the blood was so small as not to constitute decided leukæmia, whilst the spleen was still large after the short course of phosphorous on which a favourable verdict had been given.

Dr. BROADBENT said that, though he was responsible for the use of phosphorus in leukæmia, he did not consider it a certain cure. He should dismiss the first case as one of cancer, and not leukæmia. As regards the second case, he should wish to know in what form the phosphorus was given. He considered its administration valueless if given with mucilage, or with cod-liver oil, or as coated pills. He considered that phosphorus should reach the blood as such, and should be given dissolved in oil and enclosed in capsules. In Dr. Fox's case the amendment was coincident with the employment of phosphorus. He then narrated a case in which phosphorus had produced an amount of fever and of pain over the spleen followed by softening of the organ.

Sir WILLIAM JENNER doubted the existence of leukæmia lymphatica. He agreed with Dr. Moxon that the excess of white corpuscles in the medulla of bones was probably due to the choking of the venules by the white cells. He had given phosphorus 1-30th grain in pill three times a day without any effect. If the Pharmacopœial preparation was not efficacious, it ought to be at once ascertained what was the right preparation—ignorance on such a subject would be a disgrace to medical science.

Mr. SPENCER WATSON remarked that he had observed œdema of the retina in cases of anæmia.

Dr. MOXON, in reply, stated that he believed a special form of retinitis did occur in these cases. The preparation of phosphorus he had used was the oleum phosphoratum.

MENIERE'S DISEASE.

Dr. DUFFIN related the history of a case of this disease that he had observed for two years. Besides great degradation of hearing, the man was liable to paroxysms of subjective noises in the right ear, associated with fits of vertigo and a tendency to fall to the right. Skull-vibrations to a tuning-fork were almost, if not quite, absent on the affected side, although the whole range of the pianoforte could be dimly followed. After eighteen months, considerable amelioration set in; but the left ear then became somewhat involved, and the vertigo tended to throw him towards his left side. In one of his later fits, the patient for the first time lost consciousness, but without any other indication of epilepsy. Dr Duffin remarked on the pathology of the vertigo, alluding to three fatal cases of injury to the labyrinth recorded by Knapp, and to Dr. Lockhart Clarke's researches on the cerebellar and vagus connections of the roots of the acoustic nerve. He also described the effect of pressure on the vagus of his patient, which was to throw the man into a faint, and to slow his heart during recovery. He then alluded to the functions of the cochlea, and the value of musical intervals in the appreciation of the duration of time. Lastly, he alluded to the prognostic value of skull-vibrations in suspected disease of the labyrinth.

Dr. HUGHLINGS JACKSON had been consulted by many persons with this disease, who refused to believe that the ear had anything to do with the symptoms. He believed the cochlea was instrumental in the perception of sounds, and of intervals of time, and that many diseases, among which might be mentioned hæmorrhage into the ear, would produce the symptoms. With regard to patients falling, he mentioned the case of a gentleman who, whilst shooting, heard a noise in the right ear, and was afterwards deaf with that ear, but he always in walking tended to the left.

Mr. DALBY had frequently noticed giddiness and tinnitus associated with deafness. He divided them into two classes—1, in which deafness followed upon an attack of giddiness; 2, in which tinnitus and partial deafness followed at intervals upon giddiness. He narrated the case of a person who, listening to music, became giddy, and lost the power of hearing the high notes. In cases of periodically recurring giddiness he could define the exact line of notes which could be heard. He believed the labyrinth to be affected in all such cases.

Dr. FERRIER remarked that the cochlea hears aërial sounds, and the semi-circular canals are sensible to vibrations of the skull as from a tuning-fork. In this way a person suffering from vertigo, with the semi-circular canals affected, would hear aërial sounds, though insensible to vibrations of the skull. He considered that the body always fell to the side opposite the seat of irritation.

SURGICAL SOCIETY OF IRELAND.

THE sixth meeting of the session was held on Friday, 18th February, 1876, Mr. HAMILTON, President of the Society, in the chair.

Mr. W. I. WHEELER read a paper on

THROMBOSIS,

which will be found at page 215.

Dr. HENRY KENNEDY considered the subject one of great interest and one of great extent. He thought the disease occurred in several forms—1st, where there was but little pain and hardly any inflammation, and where the patient complained more of stiffness than of downright pain; 2nd, where there was a little pain and some symptoms of fever; and 3rd, what might be regarded as the suppurative form. The adhesive process was probably a rarity, and he could not take upon himself to say that he had ever seen a vein clogged altogether by adhesive lymph. He believed the disease was more common than was generally thought. It was common in the swelled leg that followed delivery. He had seen it in every disease. He had seen it in phthisis, in chronic and acute dysentery, in fevers particularly, and in pneumonia. Very lately he had a case in which the patient was afflicted with hemiplegia, and when recovering from it, he was attacked with this affection and had very severe pains in the veins of the right leg, in which there was great swelling, and accompanied by very considerable fever. That patient was now, however, recovering. He (Dr. Kennedy) merely mentioned the case to show that the disease was not confined to cases of delivery, and that it occurred under very many circumstances indeed. He had often been impressed with the belief that there was a sort of diathesis in it, for he had known the disease to occur in the same person three times, not severely, but quite marked enough to show that it was the disease. With every respect for the reader of the paper, he (Dr. Kennedy) thought more could be done for the disease than he had led the meeting to suppose. He (Dr. Kennedy) had seen local bleeding resorted to with great benefit. He had again and again used leeches on the

parts with benefit to the disease. Another remedy they found in use in these cases was mercury, pushed even as far as salivation. He had seen the disease resist again and again, and when mercury was given by inunction or by the mouth, then, only would the disease yield. He thought it was very desirable to use a specific treatment. He had seen fatal cases as the result of operations, and remembered one some years ago in Steevens' Hospital, and when a part was cut, violent rigors ensued, and fever, which carred off the patient in a very short time. Subsequently it was found that the veins near the incision were literally filled up with pus. He spoke of that case because he had seen it stated in books that it was an uncommon subject, but he thought it was not. A good deal more could be said on the subject, but at that advanced hour of the evening he would not detain the meeting at any greater length.

Mr. TYRRELL regretted that some allusion had not been made to the very valuable paper on the subject contributed by the Hon. Secretary of the Society, Mr. Richardson, some years ago. Mr. Richardson had probably written the best paper on the subject in the Irish press. He (Mr. Tyrrell) did not exactly understand what Mr. Wheeler's own ideas were on the subject of thrombosis. Mr. Wheeler was able to tell the Society what various people did and thought, but he (Mr. Tyrrell) was at a loss to catch what Mr. Wheeler thought himself. It was very hard, however, for a person to form an opinion on a subject which had engaged the attention of the profoundest pathologists of the present day, and which was still in abeyance. He had not been instructed as to what Mr. Wheeler's opinions were on the subject. He (Mr. Tyrrell) did not suppose that a surgeon present at that meeting would in a case of thrombosis think of giving mercury. He did not think either that there was a surgeon who would think of leeching in cases of what was called phlebitis. He thought it would be very useful if the Hon. Secretary of the Society would remind them of the substance of his valuable paper, which appeared in the MEDICAL PRESS some years ago, and which he (Mr. Tyrrell) could not speak of now with confidence, as he had not it before him, but he had it treasured at home. He had no doubt that Mr. Richardson would remind the meeting of the substance of his paper.

Mr. RICHARDSON observed that he could hardly think his little treatise on Phlebitis and Thrombosis (*a*) deserved the very flattering enconium passed upon it so good naturedly by Mr. Tyrrell. He (Mr. Richardson) thought that the view as to the poisonous nature of the pus corpuscle in connection with the theory of pyæmia was contradicted by the comparatively recent discoveries regarding the physiology of the white blood corpuscle, because, if the two are, as some persons maintain, identical in characters, and that the blood corpuscle, when it wanders out of a vessel, by this fact alone may become a pus corpuscle, the latter can scarcely be even one of the specific poisons of pyæmia. He might mention in corroboration of the identity of the two corpuscles that there is a patient with leucæmia under Dr. Little's care in the Adelaide Hospital whose blood he (Mr. Richardson) had frequently examined. In this case there was a great excess of the white corpuscles, many of which resembled the pus corpuscles in every character. His object in publishing his paper on phlebitis was chiefly to combat the views of Cruveilhier regarding the part played by the pus corpuscle in the development of multiple abscesses, as well as his view on the nature of the purulent-looking fluid sometimes found in the centre of the thrombus. Cruveihier supposed that when pus cells got free in the circulation they were carried in the blood current to the nearest capillaries, where they were arrested, excited inflammation and abscess. When we, however, recollect that these corpuscles are probably identical with the white blood corpuscles, it is difficult to understand, when both are at the same time coursing along the same capillary, why the pus corpuscle should be arrested and the white blood corpuscle pursue its course. There is one point in connection with thrombosis of the femoral and external iliac veins, or, if you will, the phlebitis of these vessels, alluded to by Dr. Kennedy, of considerable interest. Many years ago, during the epidemic of dysentery which occurred during the potato famine, he (Mr. Richardson) and Dr. Kennedy had seen many cases of this affection occur in the chronic dysentery, and he mentioned this in support of Dr. Kennedy's opinion that in some cases at least they probably depended upon a temporary diathesis rather than that they were the result of mere local irritation only. It was well known that hepatic abscess was not seen in the dysentery observed in the South Dublin Workhouse. He (Mr. Richardson), Dr. Mayne, and Dr. Kennedy had over and over again specially sought for it in post-mortem examinations with negative results. The livers were no doubt softer than normal, but hepatic abscess was not observed. Now if the thrombosis or phlebitis of the femoral and external iliac veins depended solely on local irritation the result of irritation extending from the adjoining ulcerated intestine, it appears to me inexplicable why hepatic abscess was not observed by us when so many of the tributaries of the vena portæ actually commenced in the focus of the mischief, the intestinal ulcer. These facts certainly do not support Cruveilhier's explanation of the formation of multiple abscesses.

Mr. W. I. WHEELER, in the course of his reply, said that with regard to leeching in phlebitis, he said in his paper that it was contra-indicated, but he thought that Mr. Paget related a case of gouty phlebitis in which it had been of use. He regretted that Mr. Tyrrell did not catch the ideas which he (Mr. Wheeler) had expressed—chiefly with regard to his own case. He believed the cause of thrombosis in this case to be superfibrinisation of the blood, together with tension of the vessels. He had stated that he believed the cause of suppuration was transudation or out-wandering of the white cells of the vessels which went to the tunics or coats of the veins. The enormous quantity of pus-like bearing cells found he believed might be accounted for by the theories of Rindfleisch, that the adhesive property of the white cells permitted them to cling to the surface of the clot, or to permeate its substance, and fresh layers of clot formed over such white cells, and thus he thought that explanatory how such a large number of pus-like cells could be present. That was his (Mr. Wheeler's) idea with respect to the case he had related. He did not express any opinion as to whether Duval's or Cohnheim's theories were correct.

The Society then adjourned.

(*a*) The original paper will be found in the *Dublin Medical Press* for March 25, 1863.

Medico-Parliamentary Intelligence.

HOUSE OF COMMONS—THURSDAY.

MEDICAL DEGREES.

IN reply to Mr. Errington, Viscount SANDON stated that with regard to England considerable progress had been made in settling the basis of an arrangement for the adoption of the conjoint scheme in examinations for medical degrees, which he hoped would be satisfactory to all parties in England. With regard to Ireland and Scotland they had no such information, but he hoped that a satisfactory arrangement would be also made with regard to the sister countries. At present he was not in a position to state what legislative powers the Government might be prepared to recommend on this subject.

SCURVY ON BOARD SHIP.

In reply to Mr. Ward, Sir C. ADDERLEY stated that the Board of Trade had received information that the barque William Wilson had arrived in Penarth Roads with several cases of scurvy on board. A medical officer had been sent to inquire into the case. Into the case of the Talisman, also mentioned in the question of the hon. member, an inquiry had also been ordered. In reference to the third ship, the Black Prince, a report had been received that the scurvy was due to the dirty habits of the crew and the bad water, and it was added that the scurvy was increased in consequence of teetotalism being the habit of the crew (loud laughter) and that the men would have been better if spirits had been served out to them (renewed laughter). On the Duke of Sutherland there were no cases of scurvy, and therefore there was no report. He thought the existing penalties for insufficient or unsatisfactory provisions were quite sufficient, and therefore

he had no intention of proposing any legislation on the subject.

KNIGHTSBRIDGE BARRACKS.

On the motion that the House resolve itself into a committee of supply,

Mr. R. YORKE rose to move the following resolution: "That this house ought not to be asked to vote the first instalment of £100 000 for the proposed reconstruction of Knightsbridge Barracks without the plans prepared by Mr. Wyatt being first produced, and sufficient time being allowed for their consideration by members."

Mr. M. HENRY objected to the new plans for the barracks on sanitary grounds; the bed-rooms of the soldiers being placed over the stabling. If it was absolutely necessary to place the barracks in this particular locality it would be far better with a view to effectual sanitary regulation to take a slice off the park and construct barracks of which the country would not feel ashamed, and divert the road in front of the present barracks. He hoped the house would reconsider the subject.

Mr. GATHORNE HARDY said the proposed barracks would be erected upon the best sanitary principles, combined with architectural beauty. The plan had been examined by the Director-General of the Army Medical Department, and he had been unable to find any fault with it in a sanitary point of view, and the stables would in no way interfere with the health of soldiers, their wives and children, who would have to live over them, and if he thought otherwise he would not propose the erection of the building. In going from Knightsbridge he should be getting out of the frying-pan into the fire. The Knightsbridge opposition was bad enough, but at Kensington he should incur the hostility of the proprietors of the palatial residences in that quarter. And if he put them in the park public indignation would be aroused against it. Chelsea was condemned as a site, and if he went there the boys would have to be removed to another building, and the pensioners would have to be sent home at a great expense. The year 1873 had been seized on as showing the great amount of sickness in Knightshridge Barracks, but if the average had been taken for ten years it would have been found that the amount of sickness there was pretty much that of other barracks, and it should be remembered that big men were more subject to consumptive disease than small men. On the whole the men at Knightsbridge were as healthy as the troops stationed in other barracks.

The motion was carried by a large majority.

INSANITARY BARRACKS.

Mr. A. M'ARTHUR called attention to the overcrowded state of the barracks in various parts of the kingdom, and expressed regret that the Secretary for War had not included in his statement to the house any proposal for improving the present accommodation of the soldiers in those barracks. There were, he would admit, difficulties in the way of carrying out improvements in this respect, at some of the barracks, where the space was limited, but that was not the case at Aldershot and other places, where the room was abundant. He thought that from £200,000 to £300,000 might be well spent in increasing the comfort of soldiers at those places, instead of devoting the money to increasing the army, because he believed it would hold out an inducement to men to stay longer in the service than they did now.

Lord E. CECIL said the Secretary for War had had this subject under his consideration for some time, and it was one in which his right hon. friend took a great interest. As the hon. member had admitted, there were difficulties to contend with, such as the peculiar construction of casemates and the difficulty of ventilation, and very little could be done under the circumstances; but what little could be done would be done by his right hon. friend.

ARMY MEDICAL OFFICERS.

On Friday last, Mr. HARDY in reply to a question from Dr. L. Playfair whether he proposed to lay upon the table any explanatory papers showing how far the proposed changes in regard tothe new army medical officers would affect the future pay of surgeons who had entered under the old rules, said that the warrant would very speedily be ready, and in the hands of hon. members, showing how the old and new surgeons would be affected by it. With regard to the surgeons who entered under the old rules, their future prospects would be very much affected by their promotion. He could not say what bearing the proposed change was likely to have on the long service of medical officers in India and in the navy. That would have to be tested by the operation of the new rules.

SHORT SERVICE FOR THE ARMY MEDICAL DEPARTMENT.

THE proposal of short service for the Army Medical Department must be regarded from three points of view—viz., its effect upon the army, the student, and the Exchequer.

Under it the service will become a "devil's acre" for the sowing of the wild oats of successive generations of recently-qualified medical students, since there are no grounds for assuming that young medical men between the ages of twenty-two and thirty-two years are more of angels than young men of any other profession.

Being only *in* the service, and not *of* the service, they will be devoid of *esprit de corps*, regardless of discipline, and indifferent to the opinions of their seniors, and will at the end of ten years return to civil life having acquired expensive tastes, restless habits, and but little professional experience, owing to an inevitable connection for five years with a regiment from which the sick will have been sent to the station hospital, and in which their only duties will consist of making sanitary inspections and conducting the teething process of the regimental babies.

The effect on the student will be that when he compares the grand solid prizes of the Indian Medical Service, and the permanent pensions of the Naval Medical Department with the temporary allurements of the short service scheme, and considers how little chance he, on returning to civil life, even with his magic £1,000, and probably with an injured constitution, would have against a contemporary who during his absence had been making a solid local basis for further professional success, he will eschew Mr. Hardy's gilded bait and seek a more lasting provision; nor would the student's father care to see his son adopt a quarter-life career from which he is to be returned to make a second start for bread at the age of thirty-three or thirty-four years, with perhaps the appendage of a wife whom he met in his wanderings.

As regards the cost to the country, the new bonus scheme will be found to be more than twice as expensive as the old pension system.

Take an example: It is required to provide for the duties of a medical officer for twenty-five years. Under the old system one man served twenty-five years and received a pension valued in commuting at £4,000.

Under the new scheme, to accomplish twenty-five years—

One man serves from	1st	to 10th	year and receives	£1,000
Second ,,	10th	to 20th	,, ,,	£1,000
Third ,,	20th	to 25th	,, ,,	£500

Apparent amount for twenty-five years' work ...	£2,500
But Government loses the interest of the first £1,000 from tenth to twenty-fifth year	£750
And the interest of the second £1,000 from the twentieth to the twenty-fifth year	£250
And compound interest on foregoing	£250
Real cost of twenty-five years' work	£3,750

But again, the rate of mortality increases as about three or four to one during the period from the tenth to the twenty-fifth year of service, as compared with the period from the first to the tenth year, therefore for every *one* man who will live to claim his commutable pension of £4,000, *three or four* will draw the *ad interim* payments amounting in value from interest and compound interest to £3,750, and so the State loses the benefit of the pensions that are never drawn owing to the death of those who have fallen short of the required number of years service.

The scheme is therefore a financial fallacy,

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 15, 1876.

EXTERN EXAMINERS IN DUBLIN UNIVERSITY.

In a recent issue we noticed the adoption of four resolutions by the Board of Trinity College as instructions to the Medical Registrar for the carrying out of certain important changes in the Degrees and Examinations of the University of Dublin. The resolutions were substantially as follows :—

1. To appoint two Extern Examiners to help in the M.B. examination. By a subsequent letter the Board authorised the appointment of three, and they were accordingly chosen.

2. To remove Surgery and Midwifery from the M.B. examination, and to create instead a new Licence in Midwifery similar to that in Surgery.

In addition to these two orders the Board had previously ordered on the 17th of October, 1874—

"That the Senior Lecturer, in conjunction with the Medial Registrar, be directed to recommend Examiners to assist the Professors in the Medical School at the examinations in Botany, Physics, Chemistry, and Materia Medica."

These resolutions of the Board came before the University Council on the 9th of February, and were referred by them to the Professors in the School of Physic for report, and accordingly the Medical Registrar (by instruction from the Board) summoned meetings of the Professors to consider the foregoing resolution. Those meetings were held on the 15th, 17th, and 22nd of February, and at the meeting held on the 15th inst. it was resolved—

"That the Professors of the School of Physic recommend the Board to direct the Senior Lecturer to withdraw the notice for the examination for the M.B. Degree recently published, and to issue an amended notice assigning the subjects for the Examination and the Examiners, as in the notices issued for the Examinations in June and December, 1875 ; inasmuch as the resolutions of the Board relating to changes in the Examinations and Examiners for the M.B. Degree are still under the consideration of the University Council."

At the meeting held on the 17th inst., the following letter from the Board was read :—

"17*th February*, 1876.

"My dear Dr. Haughton,

"I communicated the resolution of the Professors to the Board yesterday.

"The Board see no sufficient reason for rescinding their order of the 17th ult., which was framed in accordance with the recommendation of the General Medical Council.

"The Board have had no communication from the Academic Council on the subject as yet. And if any modification of the system of examination shall be hereafter recommended by that body, it will, of course, be duly considered before the next occasion for appointing Examiners.

"Yours, very sincerely,
"Andrew S. Hart.

"Rev. Samuel Haughton, M.D., Medical Registrar."

The Professors then took into consideration the resolution of Council, and—

1. Resolved, "That the Professors object to the Board's having taken final action in relation to the proposed changes in the M.B. Examination, while the question was still under the consideration of the University Council.

2. "That the Professors object to the Board making so important a change in the Examination without consulting them.

3. "That the Professors object to the want of due notice of the change being given to the students.

4. "That the appointment of Examiners, whose terms of office, duties, responsibilities, and salaries are unknown, is objectionable, and not in conformity with the usages of the University.

5. "That the Professors object to the appointment as Examiners of Teachers in Medical Schools, whose interests compete with those of the School of Physic.

6. "That the appointment of Examiners by the Senior Lecturer and Medical Registrar is objectionable."

With respect to the paragraphs which refer to the creation of a Licence in Midwifery, it was—

1. Resolved, "That the Professors consider No. 2 unnecessary in the present state of the law relating to medical registration.

2. "That the Professors object to the creation of a *Licence* in Midwifery, and earnestly urge the creation of a *Degree* in Midwifery as proposed by them, unanimously, in their report of the 17th November last."

It will be observed that the Professors are at diametric variance with the Board on all points, and have distinctly raised the question as to the right of the Board to issue such instructions without the authority of the Council, and have furthermore objected, not only to the *modus* of the steps taken by the Board, but to the purpose of those steps.

As to the contest of authority between the governing bodies of the University, we have nothing to say. As to the propriety of creating a separate midwifery qualification, the Professors seem to be in accord with the Board, but they wish to have it issued not as a Licence, but as a Degree, because it could in that case be granted only to full Arts graduates—in other words, to pupils of Trinity College, and *ergo* of its medical school.

It is, however, as to the appointment of additional or "extern" examiners that the professors especially object and we have no sympathy with them in the objection, for we believe it to be unmistakably for the benefit of the profession, of the public, and of Trinity College that the professional examination should be diluted by the help of examiners unconnected with the School of Physic

The visitors of the General Medical Council have expressed a strong opinion against the system of examining candidates by the mouth of the Professor who has taught them, and we do not see on what grounds the Professors can defend such a practice. If they desired to supply the Board with a sufficient reason for insisting on the introduction of independent examiners, they could not have gone more directly to the point than they did when they promulgated the objection—

"That the Professors object to the appointment as examiners of teachers in medical schools, whose interests compete with those of the School of Physic."

By this phrase the Professors ask the Board to protect the School of Physic against fair and wholesome competition by excluding from the conduct of the examinations of the University of Dublin every one except a teacher in that school, and a more injudicious demand they could not have made. By it they acknowledge the object of keeping the examiners' borough a close one, a purpose at which rival school teachers had scarcely ventured to hint, and which they could hardly hope that the Board would attain by the sacrifice of the efficiency or fairness of the examination. If the Professors of the School of Physic—taught by experience—express openly that to admit outsiders to the Examining Court would be to bring the School of Physic within the area of competition, then, we say, the sooner a new court of exclusively extern examiners is created the better for the University—the better even for the School of Physic.

We understand that the questions which this report raises did not come before the Academic Council at its last meeting, being crushed out by other business, but that it will be fully considered at the next meeting.

REORGANISATION OF THE ARMY MEDICAL DEPARTMENT.

Mr. Hardy's proposals for the reconstruction of the Army Medical Department having been now thoroughly discussed from an English point of view, we think the time has arrived when a change so important to the Irish medical schools should be thoroughly sifted in all its bearings. As yet, however, a great deal must be conjectured, for plausible statements made in Parliament, *ad captandum vulgus*, may appear very different upon the face of a warrant. All we really know is that a staff medical system has been finally adopted, that administrative officers are to be compelled to retire at sixty years of age, and that all future candidates are to be employed for ten years only, six being selected annually for advancement into the higher ranks. With regard to the first two of these propositions, they have our unqualified approval, for a *system* is better than *no system*, or an attempt to carry out a quasi-regimental organisation which presented neither the advantages of a pure regimental or staff system. The sixty years retirement is also a decided gain to the department, and one which should have been decided upon long since, so as to place the Medical Service in this respect upon an equality with the Control and Chaplains Departments. On the 19th of May, 1873, an influential meeting of medical officers was held at the Curragh, comprising the surgeons and assistant-surgeons of the 27th, 5th, 34th, 57th, 84th, 4th Dragoon Guards, 8th Hussars, and Royal Artillery, who gave it as their unanimous opinion that, as medical officers were no longer regimental officers, they should not be rated in future by their relative rank; that choice of quarters should be according to army, not regimental seniority; that forage be continued as an appanage of rank; that officers removed from regiments be compensated; that the ages of compulsory retirement be restored; that the existing stagnation of promotion be removed by offering *liberal terms of retirement*: that medical officers be relieved from all charge of stores and equipment, and that "the chief authority, which it is so necessary that medical officers should exercise in all matters of hospital discipline and administration," should be secured to them. These propositions were adopted by the Council of the Irish Medical Association, and a Committee of the King and Queen's College of Physicians, who recommended a retiring pension of *one shilling a day for every year of full-pay service*, and that "for the honour of the profession, the Army Medical Department ought to have supreme control over its own hospitals, subject only to the military head of the district, untrammeled by the possible interference of officers who cannot be supposed capable of judging of the affairs of such institutions." If the War Office had adopted these reasonable and excellent suggestions, it would not now be placed in the ignominious position of having to bid for the refuse of the medical schools, for we do not for one moment believe that the best, or even men of mediocre ability, will waste ten years of their life for the chance of living to a legacy of a thousand pounds—the very ten years when civil practice is only to be gained, if gained at all. Seven millions have been awarded to combatant officers for the loss which they sustained in the abolition of purchase, and it is stated upon most reliable authority that a million a year will be required to accelerate promotion and retirement amongst the same class; yet a miserable dole is refused to place the medical department upon a sound and contented footing. It seems to us a most unfortunate policy to disgust by neglect the officers now in the medical service, the men who have sustained its *prestige* and underwent the vicissitudes of war and pestilence in all parts of the world. Such a course must react upon the army itself for many a year to come, and that most disastrously. With regard to future candidates, they will be in no better position than before; for the first five years they will be employed in India in all probability, where their pay will not be increased in the least, and on return to England they will draw only some thirty pounds more than at present, without the right of proceeding on to higher rank, or to a pension if invalided. A thousand pounds is a very poor compensation for such losses as these.

Now that the medical service is to be a staff service, we hope we will hear no more of regimental allowances or attachments. The first is a decided wrong, and the last incompatible with the efficient administration or roster of a general staff. We should, in addition, like to see the corps re-embodied under its old designation of Army Medical Staff; the name of a Department has been ever distasteful, and if only a limited number are to be admitted to the higher ranks, we certainly hold to the opinion that in a scientific service the proper way would be to have the vacancies competed for, so that a young

officer on entering the service might feel that if he made himself the *best man* he must succeed in the profession which he adopted.

We have only to say, in concluding, that we are not among those who are hopeless as to the future of the medical service. The darkest day is sooner or later followed by a bright gleam of sunshine, and if medical officers will only be unanimous in insisting upon their just rights, and those which their old teachers and friends have asked for them, they must at last succeed. We have only to say that, as the service is now a limited one, it is the duty of every officer to aid in every possible way in making it efficient, and to see that the success of the future will add to the many honourable traditions of the past.

THE CORONERS (DUBLIN) BILL.

THIS measure, which received its first reading last week, on the motion of Mr. A. M. Sullivan, is worthy of earnest consideration rather for what it does not contain than for what it does.

With the exception of such alterations as are requisite to limit the operation of the measure to the City of Dublin, and to make provision for cases in which inquests are not considered necessary, together with a clause reducing the number of Coroners, this Bill is merely a reproduction of the County Coroners Bill introduced by Mr. Vance and Sir John Gray which passed the second reading last session.

The main principles of the "County Coroners Bill" had long been in force in the City of Dublin, the only new features being clause 7 of the present Bill, authorising the discharge of a jury unable to agree to a verdict, and clause 8, having reference to the committal of suspectep persons.

Mr. Sullivan's Bill provides :—

1. For power to the Coroner to appoint a deputy.
2. That a Coronor must be a qualified medical man, a barrister, an attorney, or a J. P.
3. That he shall be paid by salary, not by fees, the salary being at a minimum, equivalent to £2 10s. per inquest held for an average of five years, and £1 for each preliminary inquiry, and he shall be paid in addition his travelling expenses.
4. That he shall be entitled to retire at 60 years of age, after 21 years' service.

The Bill carries, however, its sting in its tail, for in the last clause we find a proviso that, "on the death, retirement, or disability of either of the two Dublin Coroners," the vacancy shall not be filled up, and the salary of the sole Coroner shall be raised to at least £500, and not more than £ 700.

It may be interesting in connection with this clause to observe that the two Dublin Coroners at present are Dr. William White and Dr. Nicholas Whyte, and that the "retirement or disability by reason of ill-health" of the former is imminent, so that, if the Bill becomes law, the remaining Coroner may look for a speedy accomplishment of the "not less than £500 and not more than £700 per annum." Medically speaking, we have not the least objection to his obtaining it, but would be glad to see the Dublin Coroner well paid ; but it is another matter altogether for us to acquiesce in the abolition of the Coronership, to which we most emphatically demur.

There are, however, other points in respect of which the Dublin Coroners system sorely needs amendment, and as reform is in hand, the time has arrived for the Irish Medical Association and the profession to act with vigour towards the overthrow of the disgraceful and illegal system which corporate jobbery has so long permitted to exist in Dublin. According to the letter of the law which regulates Irish inquests, and according to universal habit in London and elsewhere, the Coroner calls for the evidence of the practitioner who has been in attendance upon the deceased, or who resides, as the Act says "at or near the place" of inquest. The intention and meaning of this enactment was, obviously, that the best information as to the cause of death should be at the disposal of the jury ; but how is it interpreted in some parts of Ireland, and especially in Dublin? In that city the medical witness who could throw light on the cause of death is systematically excluded ; his evidence is, except on rare occasions, never heard, and in his stead, a practititioner who never saw the deceased, and is in absolute ignorance of the circumstances, is summoned as a witness in every case. No doubt the Coroner calls for the services of this gentleman because he is an expert—a medical jurist whose opinion is of great value, and whose *post-mortem* examination may be received with great confidence. Not at all! The Coroner's adviser is an apothecary, who, we believe, makes no pretension to any special qualification to give evidence except that he is a chum of the Coroner. He does not reside "at or near the place" in the sense in which the Legislature used the words, but the requirements of the law are usually satisfied by the bringing of the body to the morgue near which he lives. In Dublin we assert that inquests are usually held without any reliable medical testimony—*post-mortem* examinations are held in cases in which they would be perfectly unnecessary if the evidence of the medical man who had knowledge of the cause of death were had—and, as a consequence, verdicts are given which are ludicrous in their inaccuracy, and crime may go unpunished because the real causes of death are unknown.

We believe that the system which has hitherto existed is illegal, and that the fees for medical evidence might be set aside by an application to the fiating judge. If Mr. Sullivan's Bill proceeds, the Council of the Irish Medical Association should take peremptory steps to have a clause inserted which will properly define the person from whom medical evidence may be received—to secure to the medical profession their right to be heard as witnesses—to afford to Dublin juries something like reliable medical testimony as to the cause of death, and, lastly, to overthrow the corrupt compact under which the inquest law has been so long mal-administered. We shall return to this subject when occasion offers.

Notes on Current Topics.

The Fever Huts at Woolwich.

THE soldiers' huts on Woolwich Common, which have been so frequently referred to in our columns, and which

were emptied of their tenants by an epidemic of fever which compelled the survivors to take flight, are now being demolished. Various experimental efforts have been made to patch and repair them, but it was impossible to get rid of the damp and rot, and they are to be entirely swept away. Provision is made in the Army Estimates to spend £8,600 in married soldiers' quarters this year.

Boulevards in London.

A MEMORIAL signed by all the inhabitants of the Camden Road has been presented before the Local Board of Works, urging the desirability of planting trees along that wide thoroughfare. If carried out, a boulevard upwards of two miles in length will be created. There are many wide streets, not only in London, but in all the principal towns of Great Britain and Ireland, which would be greatly improved by a show of green. Trees which annually shed their bark have been known to thrive wonderfully in towns, so that the smoky atmosphere can be no longer pleaded as an excuse. In our last we referred to the effects of colours on the mind, and the surroundings of a man upon his spirits.

The dismal architecture and soot-begrimed walls of our towns tend to depress; but this tendency could be greatly counteracted by the cultivation of a few trees and plants in the larger thoroughfares and numerous open spaces.

Borax.

IT has been announced at the French Academy that a large supply of borax has been lately discovered in California, and it is asserted that in the neighbourhood in which the borax abounds animal matters will not decay. Horses have been buried for a period of four months, and when exhumed, although the heat was tropical, the flesh was in a perfect state of preservation, the hair in no part separating from the skin. It is proposed to use this mineral as a disinfectant, and for purposes of preservation of organic substances, such as butter, milk, &c.

Adulteration Fraud.

ANOTHER "milk of sulphur" prosecution took place a fortnight ago, the Justices of the Peace being the tribunal, and the Coleshill Police Court the temple of the blind goddess. There was no dispute as to the fact that the article sold as "milk of sulphur" contained 60 per cent. of plaster of Paris, but the usual wrangle took place as to whether it is lawful to sell this mixture as milk of sulphur. The wiseacres of the bench—more in their proper place one would think in growing turnips than deciding questions of adulterstion law—came to the determination that the prosecution must fail, because there are, in their opinion, "two articles known *to the trade*, as milk of sulphur and sulphur precipitatum and that the article sold was a fair sample of the former."

Oh, most righteous judges! But what has the knowledge of the trade to do with the question? Does the buying public know anything about the distinction? Does the consumer know that he is getting two-thirds of his weight in plaster of Paris, and if he did, would he buy? Not at all. He asks for what he understands to be sulphur; pays what he believes to be the price of sulphur; is led to believe that he gets sulphur; and, obviously, would accept nothing else than sulphur for medicinal purposes, if he did know it; and, therefore he is simply cheated when plaster of Paris is given him instead. The fact that the druggist knows what he is selling only makes his responsibility the greater, and the only possible excuse for the sale would be that the purchaser was aware of the nature of what he bought. The pseudonym "milk of sulphur" does not convey this information, and is, in fact, specially used to deceive, and whatever the trade may call it, the transaction is unmitigated roguery, and the perpetrators and apologists for it ought to be ashamed to call themselves honest men.

English Registrars of Births and Quack Medicine.

THE *Students' Journal* understands that in some districts registrars of births are in the habit of giving circulars respecting the virtues of Atkinson and Barker's "Infants' Preservative" to mothers when they register the births of their infants. It will be remembered that in a late number we reported the death of a child from an overdose of this nostrum. It is highly improper that public officers should interest themselves in the sale of any kind of quack medicine, but when that medicine has been shown to be a dangerous one, such conduct deserves the strongest censure.

We must do Irish Registrars the justice to say that such a practice could not exist even in the poorest district, and that any proposal to a dispensary medical officer to make money by such means would be treated with scorn. If it be right for Registrars to tout for Infants' Preservative, we see no reason why they should not accept office as agents for baby-clothes, or violet powder and puffs.

Metropolitan Asylums Board.

AN important and fully attended meeting of this Board was held on Saturday last, for the purpose of receiving the report of the chairman, Dr. Brewer, for the past year. This document presented matters of great public interest, and contained besides an analysis of the operations of the managers during the year 1875, a review of the principal events in which they had been interested during the last five years, that being the period since which any general report had been presented. In the review of the former period, one of the principal topics touched upon was the virulent epidemic of small-pox with which the managers had had to deal. It showed that in 1871 no less than 13,087 small-pox patients were admitted into the several hospitals of the board, and 2,995 in 1872, making a total of 16,082 patients treated, and 3,020 deaths in the two years. The demand for increased accommodation for imbeciles had compelled an increase of accommodation at Leavesden and Caterham, each of which establishments now provided about 2,000 beds, with provision for a third asylum at Darenth, where the board were erecting schools for imbecile children at a cost of £75,000. At the commencement of 1875 there were 4,183 imbecile patients under care of the managers, and during the year 870 fresh cases admitted, making a total of 5,053 patients under treatment. The deaths had been 540, leaving at the end of the year 4,294 patients. The agitation got up in reference to the Hampstead Hospital, and to the report of the select committee of the House of Commons was also touched upon. The next point was the administration of

the hospitals under care of the board for infections diseases, and a reference was made to the gratifying fact that, although at the commencement of the year there were 25 cases of small-pox under treatment, and that 109 had been admitted during the year, of whom 20 had died and 114 had been discharged, they had dwindled down so that, in the third quarter, there were but fifteen admissions and no deaths; that during the last quarter there were no admissions, and that, after the first three weeks of the quarter, the hospital was empty. The total number of fever patients under the care of the managers during the year 1875 was 2,149, and the total admissions 1838, as against 2,134 in 1874. In conclusion, the chairman expressed his firm conviction that the mastery over the difficulties which have taxed the energies of the managers in the past gives fair promise that the devotion and experience of the board will not be inadequate to cope with any duties which may devolve upon them in future.

The Medical Benevolent College and Charity Voting.

THE efforts of the Charity Voting Reform Association have been, we are glad to find, already attended with a considerable amount of success. The latest concession made to the appeal of this Society has come from the Medical Benevolent College. The Council, we are informed, acting in conformity with the wishes of 2,098 of its subscribers, have resolved at once to abolish the public polling-day for the election of pensioners and foundation scholars; and it will therefore be necessary that all balloting papers be sent direct to the office properly signed, and with figures indicating the candidate or candidates to be voted, for at least three days before the annual general meeting at which the result of the election will be declared. This will in some measure satisfy those who have experienced the evils of the public polling-day, and the open parading of private woes before the eyes of the benevolent, and which has greatly tended to foster the baneful system of trafficking in votes.

We wish the Council had the courage to carry out other reforms suggested by the Charity Voting Reform Association, as that of prohibiting all canvassing for votes, since it must be as apparent to the Council as it is to a large body of the subscribers, that the most destitute, and therefore the most deserving, have neither friends to devote the time, nor the money to spend, which the canvassing system necessitates. No less than 879 of the subscribers to the Medical Benevolent College refuse to have their addresses published, because they will not be canvassed, and wish to relieve themselves from unwittingly doing injustice by having to make a preference without any materials for a proper judgment upon the claims of candidates being furnished by the Council. By a small additional trouble a classified list might be sent out, which would save the friends of candidates from much harass and the expenses of a contested election. It is apparent that the voting system is based upon and lives by these long lists of candidates, who are thus converted into canvassers by themselves and their friends solely under the plea of expediency and to benefit the funds of the charity. But it is quite a mistake to suppose that all that is received under the voting system is pure gain. Such full experience has now been had of the evils of that system that it is known to repel at least as many as it attracts, as shown by the numbers who, to avoid being canvassed, will not have their addresses published, and by a large number of the most liberal class of givers who so strongly disapprove of the system that they will no longer subscribe.

The Doctor and the Grocer.

DURING the adjourned debate on the Army Estimates on Monday the 6th inst., Mr. Hardy, in reply to the statement of Mr. Dunbar, "that a medical practice could not be purchased in Ireland," announced that "he was quite taken aback at the assertion, since, judging from tenant right, Ireland was, of all countries, that in which goodwill was saleable, and he could not help thinking that as a *grocer* who had made a good business and wished to dispose of it could easily find a purchaser, so a surgeon might easily buy a business in the same manner."

Were Mr. Hardy's attention recalled to these words, he would most probably assert that to his logical mind the analogy was complete. Hitherto, however, by courtesy, the doctor's customers have been called patients, and his business a profession, and if this courtesy be continued the analogy cannot be said to hold; but if this courtesy is to be abandoned, there is no saying to what lengths of rudeness similes may not go, nor how rough social intercourse may not become. For if hereafter forms of expression are to be dictatedby logic solely, and not governed by good taste, Dr. Kenealy will cease to usurp the monopoly of stronglanguage in the House of Commons.

It was, to say the least, impolitic on the part of Mr. Hardy to express publicly his contempt for the social standing of the medical profession, when he has failed ever since his accession to office to attract the required number of its members to the army; nor will he further this object much among the Irish students by his ill-timed facetiousness in saying that, "as to Irishmen leaving the service at ten years, he was persuaded they were so talented that all would be selected for promotion, and ultimately we should have all the deputy-surgeons and surgeons-general easily recognisable by their elegant brogues."

Mr. Dunbar but stated a simple truth in saying that practices were not purchaseable in Ireland, and that consequently the possibility of an Irish student starting afresh in civil life after ten years absence in the army was proportionally less than the opportunity which an English student had, and that relatively the new proposals were to the disadvantage of the Irish.

We publish in another column a short analysis of the "effect of the new scheme on the army, the student, and the Exchequer," and cannot help thinking that, as far as Irish candidates are concerned, the army will have to wait till the Indian service and the navy are supplied.

The Registration of Midwives.

A DEPUTATION, consisting of members of the medical profession, waited upon the Lord President of the Privy Council and the President of the Local Government Board, for the purpose of recommending that steps should

be taken for securing to the public efficient women as midwives, and so prevent the undue rate of infant mortality which existed in this country. The deputation consisted of Dr. W. O. Priestley, President of the Obstetrical Society, Dr. Arthur Farre, Drs. Cleveland, Aveling, Potter, Gregg, Roper, Cooper, Rose, Tilt, Galabin, Butt, Curgenven, J. Williams, Mr. Ernest Hart, Francis Fowke, Rev. Oscar Thorpe, Drs. Wiltshire and Arthur Edis (hon. secs.), Mr. Hextall Smith, C. W. Ryalls, LL.D. (general secretaries Social Science Association), Drs. Holman, Graily Hewitt, Braxton Hicks, and many others, who were introduced to the Duke of Richmond and Gordon by Dr. Lyon Playfair, M.P., who stated that, although England was not the lowest among the nations with regard to infant mortality, yet there were other nations, especially Scandinavia, where the infant mortality was less than our own. One great cause of the mortality was the having ignorant women as midvives, and it was to this point the deputation wished to direct his Grace's attention. The employment of inefficient midwives not only tended to the destruction of infant life, but it bore upon the health of the mothers, who constantly fell into a bad state from the treatment of the nurses, and so became a burden to the family, and very often to the public as well.

His Grace the Duke of Richmond said they seldom received in that department deputations composed of men who were more competent to speak upon the subject which they had at heart than the members of the present deputation. He thought that with regard to the preservation of infant life, registration and education of midwives would not prevent the midwives keeping illicit establishments, unless it attracted a better and superior class of persons, whose ideas of right and wrong were more sensitive than the class of women referred to. He assured them that the Government were quite alive to the subject, as a proof of which he had directed a letter to be written to the Medical Council to ascertain their views on the medical education of women, and the licensing and registration of midwives. He thought the importance of the subject was equalled only by the difficulty of legislating upon it.

The Anti-Vivisection Societies.

It appears that we are beset by at least two rival anti-vivisection societies, and the secretaries at least are busily engaged in touting for funds wherewith to pay for keeping up the sensational and often untruthful advertisements which almost daily appear in the columns of the daily press. The secretaries, however, like the famous Kilkenny cats, seem bent upon performing vivisection on each other; for we gather from a correspondence in the *Morning Post* that each claims to be the real Simon Pure, and intimating their rivals to be impostors. We are informed that the emotional Jesse is no longer secretary; but this has been followed by an indignant statement that this is "unwarrantable and unjust towards Jesse, who created the society," and so forth. We have been made painfully aware of this fact, from the evidence given by Mr. J. M. Holt, M.P., before the Royal Commission. This gentleman has been held forth as a member of Mr. Jesse's committee; but when pressed to give some account of the society, he was unable to do so, and said that the person who "created the society" was treasurer, secretary, chairman of committee, and everything else; in short, that the society had no real existence except in the brain of Jesse, who undertook without a committee "to express opinion on behalf of the society and without asking for authority" from those whose names so prominently figure in his precious society. When pressed by a member of the Commission to say whether the letters sent out in the names of respectable gentlemen had ever been shown or submitted to them, Mr. Holt declared they had not, for no meeting of any committee had ever taken place, and he emphatically added that the action of Mr. Jesse with regard to the doings of this precious society had been entirely Jesse's own affair, for he appointed president and committee, and received subscriptions in the name of a society, which had no real existence; and although he had protested against the informal proceedings of Jesse, he still went on, and had the audacity to present himself to the Royal Commission as the representative of this sham society. It is, we think, right that the public should know how such societies are got up, and who it is pull the strings and find money for this bare-faced agitation upon vivisection.

The Queen at the London Hospital.

In our last we announced the visit of her Majesty for the purpose of formally opening the new wing for which the Grocers' Company had voted the magnificent sum of £20,000. The hearty welcome accorded to her Majesty by the vast population of the East End, and the appropriate and universal decorations along the route through which the procession passed, are now matters of history. To that which we stated in our last we have only now to add some few particulars of the reception inside the walls, which we were unable to give fully in our last, in consequence of going to press. His Royal Highness the Duke of Cambridge, as President of the Hospital, was there to receive the Queen, with his Grace the Archbishop of Canterbury, the Lord Mayor, and other notabilities, together with the Treasurer, Vice-Presidents, and staff of the hospital. There was a short religious service, including a chorale composed by the late Prince Consort, with appropriate prayers; and after the presentation of an address and a suitable reply, the Home Secretary, by command of her Majesty, declared the new wing of the Grocers' Company open. Several of the company present had the honour of presentation, amongst them being Dr. Andrew Clark, Senior Physician; Mr. Jonathan Hutchinson, Senior Surgeon; Mr. Nixon, House Governor; Mr. Snelgrove, Secretary, &c. The Queen then passed through the new wards and some of the old ones which had not been prepared for her reception, showing her kindly interest in the welfare of the patients by words of encouragement and consolation to the adults, and patting the cheeks of the juveniles. On this account, if on no other, her Majesty's visit is not likely to be forgotten for the next generation, and the motto outside the walls, "A humane Queen makes a loving people," was singularly appropriate on the present occasion. Nor was royal sympathy shown in words only; the handsome donation of 500

guineas being a further proof of her interest in the sick and afflicted. As mentioned in our last, the weather was magnificent, and the arrangements everything that could be desired—so well managed, in fact, as to call forth a tribute of her Majesty's admiration.

The Medical Society of London.

THE 103rd anniversary dinner of this excellent Society took place on Wednesday last. A very large body of the Fellows rallied round the President, Dr. Routh, on the occasion. The toast of the "Corporate Bodies" was given by Dr. Richardson in appropriate terms; this was warmly received and eloquently responded to by Sir James Paget, the President of the College of Surgeons. The learned societies found an admirable representative in the person of Mr. Gynn Jefferys, one of the oldest Fellows of the Royal, who alluded to the excellent scientific work performed by members of the medical profession. The social character of the gathering was much promoted by the excellent music contributed by some of the younger Fellows of the Society. Mr. Wm. Adams, F.R.C.S., is the newly-elected President of the Society for the ensuing year.

Sham Charities.

WE are pleased to observe that the Charity Organisation Society has resolved to adopt means of warning the public in respect to sham charities, those which it has taken means to ascertain are unworthy of public support.

Election at the Royal College of Surgeons of England.

THE election of a member of the Board of Examiners in place of the late Mr. Gascoyne will shortly take place. For the purpose of selecting from among the large number of candidates a committee has been formed, and we hear that this committee has returned the name of only one candidate. Now it does not appear to us that the duty of the selecting committee is to return the exact number of candidates according to the vacancies to be filled, for in that case the committee becomes virtually one of election, and not of selection, and it will not satisfy the Fellows of the College that the Council should give the power of election of its examiners into the hands of only three of its members. Such an arrangement is too open to partiality and intrigue, and cannot certainly be countenanced by the Fellows.

On looking to the supposed great reform which has lately taken place in the mode of examination at the College of Surgeons, we conclude that the new Board of Examiners was constituted in order that the examiners in anatomy and physiology should be chosen from among those who have had experience in teaching those subjects, and who are therefore considered capable of examining in them.

In this way it was thought to relieve the Court of Examiners of a tedious and difficult part of their duty, and at the same time to greatly improve the examination, against which we must add there has been up to the present time a just cause for complaint.

Now have the selecting committee impartially and otherwise fairly performed their duty on this occasion? We hear that they have returned the name of only one candidate, and that that candidate has no claim to be considered either a teacher of anatomy or physiology. The name of only one candidate is sent up to the Council for election, and the Council must either elect that candidate or altogether ignore the existence of the committee of selection in whom they have relied for an impartial valuation of the claims of the several candidates for the position of honour. We have not a word to say against the fortunate individual who has been selected by the committee, an able and scientific surgeon, well worthy a position of honour; but on these accounts he claims no right to the Examinership in Anatomy and Physiology. It is impossible now for the committee to reconsider their selection, which must be either approved of or rejected by the Council, who in turn are responsible for the judicious execution of the trust confided in them by the Fellows.

Prescribing Druggists and the Defence Association.

THE successful prosecution of a prescribing druggist at the East end of London by the Medical Defence Association, and the avowed intention of the Association to deal out the same justice to others of the same fraternity, has created quite a panic amongst the "counter-physicians" of Whitechapel and its neighbourhood. The druggists who have been so long breaking the law that they seem to think they have a vested right to continue to do so have flown to the Council of the Pharmaceutical Society for refuge, and that compliant body, which took the drug adulterators and the fraudulent dispensers of Sheffield under its wing, talks of an appeal to arms to defend counter-prescribing as one of the established privileges of druggists. At the last meeting of the Councils, the Secretary read a letter addressed to the Council by a member of the Society residing at the East End of London, whose name is discreetly suppressed, calling attention to the recent decision in *The Apothecaries' Co.* v. *Nottingham*, and asking advice upon it, inasmuch as the Medical Defence Association was threatening to carry out that decision by prosecuting every chemist who might transgress the law as laid down by the judge in that case; and it was stated by a Councillor that 200 notices of prosecution in case of continuance had been served in the East End. Some of the Council were for an immediate appeal to arms, while others, remembering, perhaps, that no defence was possible, thought it better to "let sleeping dogs lie," and wait for the actual onslaught of the Defence Association. Seeing that the Council of the Pharmaceutical Society have already appeared in arms as champions of adulteration, and of dishonest dispensing, it is not surprising that they should declare in favour of counter-prescribing, especially as Mr. Baynes, one of its members, openly confessed that "he infringed the law every day." We recommend this statement (which will be found at page 713 of the *Pharmaceutical Journal* for March 4) to the attention of the Medical Defence Association, to whom we say *Macte Virtute, Puer!*

The Cashel County Infirmary.

At the last meeting of the Tipperary Grand Jury Captain Adams moved to have the presentment for the maintenance of the County Infirmary, Cashel, torn.

A lengthened discussion thereon ensued, and a poll was subsequently taken, when the motion was defeated by a majority of 13 to 5.

The Silver Medal of the Medical Society of London has been awarded to Dr. Lauder Brunton for the best paper of the year.

Sir Joseph Fayrer, C.S.I., was last week officially gazetted a Knight Commander of the Order of the Star of India.

Drs. Andrew Clark, Theodore Duke, Francis H. Laking, and Henry Maudsley, have been elected members of the Royal Institution of Great Britain.

Mr. Benjamin Lane has been duly elected Coroner for Londonderry. The newly-elected coroner, is brother to the late Dr. Wm. Lane, of Newtownlimavady, who filled the office so long.

Dr. Valentine Browne, late physician to the Mater Misericordiæ Hospital, Dublin, has been appointed physician to the hospital at Bourke, New South Wales. The appointment is said to be worth about £1,000 per annum.

It has been found necessary to close the Victoria Hospital for Sick Children for repairs and for the purpose of making certain important alterations, resulting in the addition of ten extra beds for the little patients, and greatly improved sanitary arrangements.

An extraordinary accident occurred in London during the storm on Sunday. As an empty omnibus was being driven to the stables at Islington, a telegraph wire was blown by the violence of the wind across the road, nearly severing the head of the unfortunate coachman from his body. Mr. George Brown, M.R.C.S., was immediately on the spot, but life was of course extinct, and the body thereupon removed to the parish mortuary.

The Surgeoncy of the Westmoreland Lock Hospital, at Dublin, in the room of Dr. Morgan, has attracted many competitors. The names mentioned in connection with the candidature are multitudinous. Of those who are actually in the field, we hear of Mr. Macnamara, of the Meath Hospital, Dr. Mapother, of St. Vincent's, Dr. Wheeler, of the City of Dublin Hospital, Dr. Martin, of Jervis Street, and Dr. Peele, of the South City Dispensary. The choice of a surgeon lies with the Board of Management, which consists of twenty gentlemen, twelve of whom are known to be Conservatives, and eight Liberals. It was, we understand, mooted to hold the appointment in abeyance for the present, but this proposition was negatived, and the election will take place on Saturday, the 1st of April.

Notice has been given that on Saturday, the 15th of April, the Senate of the Queens University will proceed to elect one Examiner in each of the following subjects, and at the salary stated:—

Subject.	*Salary.*
Medicine	£100
Surgery	..100
Midwifery, &c.	... 75
Materia Medica ...	... 75
Medical Jurisprudence ...	... 75

The Examinations will begin in the second week of June.

The artgoing Examiners are as follows—*Medicine*—Henry Kennedy, M.D.; Benjamin G. M'Dowell, M.D. *Surgery*—Prof. J. V. Browne; Anthony H. Corley, M.D. *Materia Medica*—Walter Smith, M.D.; Charles F. Moore, M.D. *Midwifery*—J. Rutherford Kirkpatrick; William Roe, M.D. *Medical Jurisprudence*—J. Emerson Reynolds; Matthias O'Keeffe, M.D.

The Professorship of Anatomy in the Irish College of Surgeons, vacant by the death of Professor Morgan, is the subject of close competition. The emoluments are worth between £350 and £400 a year, according as the School of the College is prosperous, or the contrary, and the candidates at present are—Dr. Thornley Stoker and Dr. Loftie Stoney, Demonstrators in the School. Mr. Corley, Lecturer on Surgery in the Carmichael School; and Mr. Charles H. Robinson, Demonstrator in the Ledwich School. The election cannot take place for at least a month, inasmuch as, by the charter of the College, the vacancy must be advertised in three papers, and 28 days must subsequently elapse before the appointment can be made. The last of the gentlemen whom we have named as candidates enumerates we are told, amongst his qualifications for the Professorship that he is an "ex-correspondent of the *Lancet* and *British Medical Journal*," in which capacity no doubt, a special aptitude for the teaching of anatomy is necessarily acquired.

Correspondence.

THE ARMY MEDICAL SCHEME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—From time to time I have read in your journal the varied schemes regarding the status and value of army medical men. I cannot look on any of the alterations proposed as tending to satisfaction. Being an old army medical officer out of the service for the last twenty years, I should not enter it again in my youth under the proposed arrangements of Mr. Gathorne Hardy for any consideration. I have served as staff and regimental officer in the service. On the first, the honorary member of regimental messes in garrison, I felt myself an outsider—"nobody's child;" as a regimental officer I was at "home," loved my regiment, respected by officers, wives, and soldiers, because I was one of their own—I knew them all professionally and privately—in fact, the family doctor, who knows by time the constituent he advises. Years roll on; I leave the service; my brother officers executive rise in rank; don't forget the comrade of their youth; and when opportunity occurs, renew the acquaintance. Can this be under Mr. Gathorne Hardy's scheme? Never! Would this worthy promoter of the proposed alteration like to be handed over in case of illness, from one who is his regular medical adviser to a stranger? Not a bit of it. How would he like his wife or children the same? Touch this gentleman home, and he won't act in private life as he proposes in public. I have much love for the military medical service, and I always found in

my day, under the direction of one of the most able army medical director-generals, the late Sir James M'Grigor, Bart., that military medical officers were all, as a rule, gentlemen by birth, education, and manners, and treated as such. My only child, a son, felt disposed to become a medical man, and wear the red coat as his father did, but he repudiated the position now offered. If the service was *as it was*, he should accept a commission, and I would allow him £500 a year, as becoming the position I held.

Yours truly,

LATE A REGIMENTAL, also STAFF MEDICAL OFFICER.

THE BILLS BEFORE PARLIAMENT.

MR. GIBSON'S Bill to put on the Register the Baccalaureate in Surgery of the University of Dublin, and to throw open the County Infirmaries to all registered surgeons is set down for its second reading for the 30th of March, and it will probably pass unopposed. The Medical Acts (Foreign Universities) Bill of Mr. Cowper-Temple, which intends to admit women holding foreign medical qualifications to the Register, is on the paper for the 5th of July; and Mr. Meldon's County Infirmaries Bill, which is to reform the administration of those institutions, and to allow superannuation to surgeons, for the 12th of the same month, which may be taken as equivalent to the Greek Kalends.

DR. PARKES, F.R.S.

THE *British Medical Journal* says: "It has been for some time known that Dr. Parkes of Netley has been suffering from prolonged illness, consequent on an attack of pneumonia and subsequent weakness. We deeply regret to learn that his present state of weakness is such as to give reason for the most serious alarm."

THE statue of Dr. Stokes, now placed in the Hall of King and Queen's College of Physicians in Ireland, is to be formally unveiled on Thursday, March 16. A very large gathering is anticipated on the interesting occasion; and among others who have promised to attend is Dr. Acland, Regius Professor of Physic at the University of Oxford.

THE seat on the Council of the Irish College of Surgeons which Dr. Morgan's lamented death vacated will probably be immediately filled up. In the terms of the charter a requisition must be made by two Fellows for the assembly of the College for the election, and in six days or more afterwards the meeting will take place. The requisition will probably be signed to-morrow (Thursday), when Council meets. Two candidates have already presented themselves—Dr. B. F. M'Dowel, Surgeon to Mercer's Hospital, and Mr. Wilson, Surgeon to St. Mark's Ophthalmic Hospital, and Professor of Ophthalmology in the College.

Literature.

THE IRISH MEDICAL DIRECTORY FOR 1876. (a)

OUR yearly visitor comes to us on this occasion having greatly increased in corpulence since we last saw it, and the present edition would seem to have thoroughly exhausted all that can be said respecting the profession in Ireland, besides not a little of what may be recorded respecting British medical affairs. The 270 pages with which the Directory started four years ago have expanded to nearly 600 pages, and even within the last year the work has been enlarged by nearly 100 pages, as was necessary to keep pace with the increased demand for the book. The Public Health Act, the recent changes in the Army and Navy Medical Departments, the new arrangements of Irish Pharmacy, and the recent legislation on adulteration, have all combined to increase the labours of the editor, and to make the work more valuable than ever to the Irish medical practitioner and to libraries in England and America. The official regulations, which affect workhouse medical officers, and the Acts of Parliament upon which those regulations have been framed, and the new Lunacy Act of last session, have been added to the Directory; and it would be difficult for us to say what information suitable to such a publication it does not contain. The compilation of the work is carried out—as the editor informs us—under great discouragement, from the obstructions interposed by the General Post Office, and the unbusiness-like habits of medical men in general, from whom it is often impossible to extract a reply to a letter, even by abject entreaties. Nevertheless the book is well done, and wonderfully accurate, comparing most favourably with another similar publication in which hundreds of names of dead or departed men appear, and from which is omitted the mention of scores of new practitioners who have settled down within recent years to Irish practice.

The book is a valuable one, almost an indispensable one to Irish medical men, and it deserves their support, not only upon its intrinsic merits, but upon the principle that a venture launched for the benefit of Irish medical men by one of themselves ought to be sustained.

(a) "The Irish Medical Directory for 1876." Dublin: Offices of the MEDICAL PRESS AND CIRCULAR, 23 Ely Place. London: Bailliere, Tindall, and Cox, 20 King William Street. Crown 8vo, pp. 552–xl.

Medical News.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,202 births and 3,934 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1000 persons living. The annual death-rate was 23 per 1000 in Edinburgh, 25 in London, 34 in Glasgow, and 39 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 23, Hull 24, Leicester 20, Sunderland 20, Portsmouth 25, Newcastle-upon-Tyne 20, Birmingham 22, Brighton 18, Leeds 24, Wolverhampton 23, Bradford 24, Sheffield 23, Plymouth 30, Bristol 24, Oldham 28, Manchester 31, Salford 32, Nottingham 27, and Liverpool 31. The annual death-rate from the seven principal zymotic diseases averaged 3·8 per 1000 in these towns, and ranged from 1·0 and 1·4 in Brighton and Wolverhampton, to 7·1 and 7·9 in Portsmouth and Salford. Scarlet fever showed fatal prevalence in Portsmouth, Bristol, Salford, and Leeds. Fourteen more deaths were referred to small-pox in Manchester and Salfor, and 9 to fever in Sheffield. In London, 1,544 deaths included one from small-pox, 45 from scarlet fever, 19 from different forms of sever, and 18 from diarrhœa; the seven principal diseases of the zymotic class causing 227 deaths, against 256 and 215 in the two preceding weeks. These 227 deaths were 7 below the corrected average number from the same diseases in the corresponding week of the last ten years. The death referred to diseases of the respiratory organs, which in the two previous weeks had been equal to 622 and 458, further declined last week to 405, which were 7 below the corrected average weekly number; 240 resulted from bronchitis, and 104 from pneumonia.

University Hospital.—The Princess of Wales paid an unannounced visit to the above hospital on Friday last.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Notice to Subscribers.—The Publishers will be glad to receive the subscriptions for the past year, 1875—£1 2s. 6d. Subscriptions in advance for 1876, at the reduced tariff of 21s. per annum, post free, must be paid before the end of this month in London, Dublin, or Edinburgh.

Reviews of Books in Type.—The following notices are unavoidably held over, and will appear as soon as space permits: "Burdwan Fever," by Dr. Roy; "Elements of Physiology," by Dr. Hermann; "Examination of Drinking Water," by Dr. Macdonald; "Rarity of Soft Chancre," by Dr. Mauriac; "Dental Anatomy," by Mr. Sewill; "The Nature of Light," by Dr. Lommel; Bentley's "Medicinal Plants;" Fox's "Skin Diseases;" "The Student's Guide to the Practice of Midwifery," by Dr. Lloyd Roberts; "Braithwaite's Retrospect of Medicine," &c., &c.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

The *Pharmaceutical Journal* never reaches our Irish Office until Monday. The publisher of our esteemed contemporary ought to be capable of observing punctuality.

Royal College of Surgeons of England.—On Wednesday and Friday, at 4 p.m., Prof. W. K. Parker will continue his lecture "On the Shoulder-girdle and Fore-limb of Vertebrata."

Royal College of Physicians of London.—On Wednesday and Friday, at 5 p.m., Dr. A. B. Shepherd will lecture "On the Natural History of Pulmonary Consumption."

State Medicine at Cambridge.—The next examination for a certificate in State Medicine at Cambridge will commence on June 13th. Candidates must send in their applications to Prof. Liveing on or before May 30th. All requests for information should be addressed to Prof. Liveing, Cambridge. Any person on the Medical Register who is twenty-four years of age may present himself for this examination.

Harveian Society.—On Thursday, at 8 p.m., Dr. Milner Fothergill, "On Neurosal Affections of the Heart."

Dr. Abbath, Sunderland.—Communication received as we were at press.

Medical Microscopical Society.—On Friday, at 8 p.m., Dr. W. B. Woodman, "Hints on the Systematic Study of Histology."

Letitia sends us a letter imploring us to aid the inhabitants of Hastings to get rid of their *leaden tanks*, as the landlords refuse to remove them. Our correspondent goes on to state that "dozens of us die every year from lead-poisoning." Is our anonymous correspondent trying to crack a joke?—if so the attempt is a very poor one—or is he sincere in his wish to consign at once all tanks to limbo in favour of the constant supply system? If the latter, we have already expressed our opinion, and cannot open our columns to the exclusive claims of any one town. In this respect Hastings is no worse off than other towns; there is no necessity for dozens to die of lead-poisoning if they will take the trouble to keep their tanks clean.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Gratuitous and Provident Medical Relief. By R. W. Griffin, M.D.

List of the Fellows, Members, and Licentiates of the Royal College of Physicians of London, 1875.

VACANCIES.

Queen's University.—Examinerships in Medicine, Surgery, Midwifery, Materia Medica, and Jurisprudence. For the value of each and other particulars see Advt.

Carlow Union, Bagenalstown Dispensary District.—Medical Officer. Salary, £100, with £20 as Sanitary Officer, with other fees. (See Advt.)

Charing Cross Hospital.—Physician or Surgeon for the Skin Department. Honorary. Applications, with Testimonials, to the Secretary.

Great Northern Hospital, Caledonian Road, N.—Physician. Honorary. Also a Dispenser. Salary, £60. Address the Secretary.

Birmingham General Hospital—Registrar and Pathologist. Salary, £130, with board and residence. Applications, with Testimonials, to the House Governor.

Bermondsey Union, Surrey.—Medical Officer of Health. Salary, £160 per annum. Applications, with Testimonials, to the Clerk at the Vestry Offices, Bermondsey, S.E.

Christ Church Union, Hants.—Medical Officer. Salary, £100 per annum, exclusive of fees. Address the Clerk to the Board of Guardians.

Kent County Lunatic Asylum.—Assistant Medical Officer and Dispenser. Salary, £120, with board and residence. Applications to Mr. Callaway, Canterbury.

Leeds General Infirmary.—House Physician. Salary, £100, with board and apartments. Address, Dr. Heaton, at the Infirmary.

Salford Hospital.—House Surgeon for the Pendleton Branch Dispensary. Salary, £100, with board and apartments. Applicants must address the Secretary.

APPOINTMENTS.

Cameron, J. S., M.D., B.Sc., has been appointed Physician to the Huddersfield Infirmary.

Cohill, J. G. Sinclair, M.D., F.R.C.P. Edin., late Lecturer on General Pathology at the Edinburgh Medical School, has been elected Physician to the Royal National Hospital for Consumption, Ventnor.

Coutts, J., L.F.P.S.Glas., Medical Officer and Public Vaccinator for the Parish of Morven, Argyllshire.

Dunbar, A., M.D., Medical Officer for the North Municipal District of the West Derby Union, Lancashire.

Ellis, J. L., L.K.Q.C.P.I. & L.M. Medical Officer for the Mallwyd District of the Dolgelley Union.

Fothergill, J. M., M.D., M.R.C.P., Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

Graham, J., M.D., C.M., Medical Officer for the Killough Dispensary District of the Downpatrick Union, co. Down.

Greenwood, T. P., M.R.C.S.E., House Surgeon and Secretary to the Stamford, Rutland, and General Infirmary.

Haward, E., M.D., M.R.C.P.L., a Physician to the North London Hospital for Consumption and Diseases of the Chest.

Hawkins, A. F., M.R.C.S., L.R.C.P., Resident Surgical Officer to the General Hospital, Birmingham.

Maguire, R. F., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the London and North-Western Railway Club, Holyhead District.

Maturin, L., L.R.C.P.I., L.K.Q.C.P.I., Medical Attendant to the Royal Irish Constabulary, Achill, and Admiralty Surgeon and Agent for the Stations of Keel, Achillbeg, Dugort, and Bull-mouth.

O'Hagan, P. J., L.R.C.S.I., Medical Officer, &c., for the Kingscourt Dispensary District of the Ballieborough Union, co. Cavan.

Prockter, A. E., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Barton-under-Needwood District of the Burton-on-Trent Union.

Wilding, W. A., M.R.C.S.E., L.K.Q.C.P.I., Junior House-Surgeon to the Borough Hospital, Birkenhead.

Births.

Bromley.—On the 7th inst., at Castle Hedingham, Essex, the wife of J. B. Bromley, M.R.C.S., &c. of a daughter.

McCoy.—On the 8th inst., at 1 Abbey View Terrace, Rathkeale, co. Limerick, the wife of Daniel F. McCoy, M.D., of a son and heir.

Sterling.—On the 5th inst., at Castlecomer, co. Kilkenny, the wife of James Sterling, M.D., of a son.

Marriage.

Turner—Davenport.—On the 9th inst., at St. Nicholas', Brighton, T. B. Turner, M.R.C.S., to Edith, daughter of J. T. Davenport, Esq., of Wyndham House, Brighton.

Deaths.

Bean.—On the 15th Feb., at Torquay, Edward Fowler Bean, M.R.C.S.E., aged 69.

Buckby.—On the 24th Feb., at Sutton-on-Trent, Arthur G. Hesilege Buckby, M.R.C.S.E., aged 50.

Coleman.—On the 10th Feb., at Galway, James Joseph Coleman, L.R.C.P.Ed., aged 31.

Cuthbert.—On the 1st March, at Gortfoyle, Londonderry, of typhus fever, caught in the discharge of his duty, Alex. Cuthbert, M.D.

Donaldson.—On the 4th March, at Crossmaglen, co. Armagh, Richard Donaldson, L.R.C.S.I.

Eager.—On the 3rd March, at Guildford, Richard Eager, M.R.C.S.E., aged 73.

Ellery.—On the 25th Feb., at Axminster, Devon, Henry James Ellery, M.D., aged 46.

Furlonge.—On the 21st Feb., at Kinsale, co. Cork, William Furlonge, M.D., aged 86.

Heffernan.—On the 2nd March, at Malta, on his way home from India, Dr. P. J. Heffernan, H.M.'s Bengal Army, third son of the late Patrick Heffernan, M.D., J.P., Cashel.

Johnson.—On the 5th March, Walter Johnson, M.R.C.S.E., of Colchester, aged 70.

Mason.—On the 8th March, at Surbiton Hill, C. I. Mason, L.R.C.P., aged 47.

Nayler.—On the 9th March, at Brighton, G. Nayler, Esq., F.R.C.S., of Savile Row, London, W., aged 48.

Rushforth.—On the 29th Feb., at Truro Road, Tottenham, Richard Rushforth, Surgeon, in practice prior to 1815, aged 77.

Simson.—On the 8th March, at Glenfinlas Street, Edinburgh, J. Simson, M.D., F.R.C.S.E.

IRISH POOR-LAW INTELLIGENCE.

DUTIES OF SANITARY OFFICERS.

TO THE EDITOR.

SIR,—In the article in your Supplement of 23rd February with respect to the payment of sanitary officers for attendance at petty sessions courts, the following paragraph appears :—"The Local Government Board state in reply to a letter of inquiry from the Drogheda Union that it is not one of the prescribed duties of the sanitary officer to attend at petty sessions to prosecute in such cases, and the question of costs is one for the magistrates to consider."

This statement, so clear and distinct, was naturally received throughout the country by the dispensary medical officers, who are *ex officio* sanitary officers, with great satisfaction; but I regret to say they are doomed to disappointment. The decision of the Local Government Board refers to *consulting* sanitary officers, and not to them, as will be seen by the enclosed letter addressed to Dr. Smyth, of Naas.

Your obedient servant,

Naas, 2nd March, 1876. ROBERT S. HAYES.

Local Government Board, Dublin,
29th February, 1876.

SIR,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 24th inst., inquiring whether it is a part of your duty as sanitary officer to attend and give evidence in cases of prosecution under the Sanitary Acts, and in reply the Board desire to draw your attention to Part II. (Executive Duties) of the General Order of the 9th September, 1874, from which you will observe that every sanitary officer is required to attend and assist in all proceedings in which his attendance or assistance may be necessary.

With regard to the case which occurred in the Drogheda Union, to which you refer, the Local Government Board have to state that their decision in this case had reference solely to the consultiug sanitary officer.

By order of the Board,
B. BANKS, Secretary.

To Dr. Smyth, Medical Officer.

The statement which we published was copied *verbatim* from a Drogheda paper, but, if it had been read with more attention by us, would have been observed to be incorrect, for we were aware that the Local Government Board have held sanitary officers responsible to attend and give evidence in sanitary prosecutions. In fact, under their sanitary orders (page 514, Irish Medical Directory) it is hard to say what they may not order the dispensary medical officer to do. Under the head of "Executive Duties" the order says :—

"1. The duty of the executive sanitary officer shall be to attend every meeting of the sanitary authority, and to take directions on the sanitary business of the Board, and on the reports of the sanitary officers, *and all proceedings arising thereon*, and to see that the same are carried out and brought to a conclusion where practicable, in pursuance of the orders of the Board.

"2. In furtherance whereof we do hereby direct that every sanitary officer and sub-officer of the Union shall, on receiving directions from the executive sanitary officer, attend and *assist in all proceedings in which his attendance or assistance may be required.*"

The word "proceedings" in clause 2 must be held to mean the proceedings referred to in clause 1, but the wording is so vague, being purposely made so, that it would include the service of processes or the cleansing of a sewer, or indeed any act which "arises" upon "the sanitary business of the Board, or on the reports of the sanitary officers." Referring to the words of the Public Health Act, under the authority of which the Local Government Board have made this sweeping order, we entertain great doubt that they possess any power to impose duties upon the sanitary officers *ad libitum*. By clause 10 it is enacted (page 487 Irish Medical Directory) that "Every medical officer of a dispensary district shall be a sanitary officer for such district, and the said Board (the Local Government) shall assign to the dispensary medical officers, and to the other sanitary officers, if any, and to the medical superintendent officer of health, if such an officer be appointed for the sanitary district, their respective duties and functions *in the discovery or inspection or removal of nuisances, in the supply of pure water, in the making or repairing of sewers and drains, or in generally superintending the execution of the sanitary laws within the district.*"

This clause, we assert, gives the Local Government Board no authority to compel sanitary officers to attend prosecutions as witnesses, or, if sworn, to give evidence without a fee. The sanitary officer is bound by it to aid in finding out a nuisance, to inspect it when found, and to help in removing it, to look after pure water supply, to superintend the making of sewers, and to "superintend" the execution of the law. The giving of evidence does not come within the term "superintend," nor does the wording of this clause justify the indefinite imposition of irrelevant functions upon the sanitary officer by the Local Government Board. This being one of the first instances in which the order of the Local Government Board as to duties of sanitary officers has been tested, it seems to us that the Irish Medical Association should consider whether it should not interpose to protect these officers from the compulsion under which they are placed to discharge a function which seems to us quite illegal.

RED TICKETS.

TO THE EDITOR.

SIR,—The admirable letter of "A Dispensary Doctor" in your issue of the 16th February, detailing the continually increasing grievances under which dispensary doctors suffer from the now almost indiscriminate and scandalous abuse in the issue of red or visiting tickets is well deserving the

most attentive consideration of the Local Government Board and the profession.

To the three classes enumerated by "Dispensary Doctor" I would add a fourth—viz., National School teachers. Now these committeemen and wardens, should they feel inclined, have at present almost unlimited power to set at defiance all the theoretical checks placed by the Legislature and Local Government Board on the issuing of tickets. Moreover, they wield at pleasure a terrible engine to annoy the doctor, and perhaps finally drive him from his district. The remedy proposed—viz., to make the party responsible for the doctor's fee in case the ticket be cancelled, is a capital one, provided the committees would act under the altered circumstances as at present. The mode of cancelling now practised is very little short of a farce, as although the dispensary regulations, &c., give ample powers to effect that object, still, if I mistake not, they compel the unfortunate doctor to attend on the issue of a fresh ticket for same case perhaps an hour afterwards.

Before leaving this part of the subject, allow me to express my surprise and condemnation of the action of the Local Government Board and the Board of National Education in permitting school teachers to act as wardens, thereby diverting their attention from the special and much more important duties of the school in filling tickets for the parents of pupils, &c.

I am glad to see a steady and increasing decline in the numbers of candidates for Irish dispensary appointments. A miserable £100 or £120 per annum and paltry shilling registration fees, with clerkship drudgery and red-tapeism attached, are evidently ceasing to attract medical men. More lucrative and independent situations can be obtained elsewhere with good prospects of promotion, and much less laborious and disagreeable duties to perform.

To add almost the last straw to the burden of the long-suffering and ill-used Irish dispensary doctor, he is now compelled to act as sanitary officer in his district for the wretched pittance of sixpence or ninepence per day, while his medical brother in England is paid from £100 to £700 per annum for like duties.

Can Dr. O'Leary obtain no remedy for the latter grievance by his eloquent and telling speeches in the British Parliament?

Until the Poor-law Medical Service is made a "*State department*," and placed entirely under the control of the executive, and the competitive system adopted *at entrance* subsequent promotion to be gained by length of service and ability), I am afraid we will still have just cause of complaint, and remain isolated, while assistant-barristers, stipendiary magistrates, and members of the constabulary force are getting large additions to their salaries and superannuation allowances, although the duties they discharge to the State are of less vital importance than those so effectively performed by the Poor-law medical officers of Ireland.

I earnestly trust the Local Government Board and the Legislature will anticipate a *dead lock* in the dispensary service by effecting reforms and insisting on a suitable scale of salaries, and certain—not permissive retiring allowances, also one month or six weeks' leave of absence each year at option and without pecuniary loss to medical officers. These reforms, combined with a complete change in the present pauperising system of issuing tickets, would at least tend to make the service more popular with medical men, and give practical effect to the maxim of every paternal government, "Salus populi suprema lex."

Yours faithfully,

ANOTHER DISPENSARY DOCTOR.

TO THE EDITOR.

SIR,—In your publication of the 16th ult. is a letter from a "Dispensary Doctor" about the abuse of dispensary tickets, and the remedies to be applied for their removal. With most of those I quite agree, but with regard to red or dispensary visiting tickets, the remedy I would suggest would be this:—The medical officer, on getting a visiting ticket for a party that in his opinion was not a fit subject for such relief, having adequate means to pay for such attendance, he would write to the honorary secretary of his committee of management, asking him to call an extraordinary meeting of its members. Of course the object of such a meeting is mentioned in the requisition. The matter could then be fairly discussed, and if the majority of the members present were of opinion that the ticket had no right to be given, the party issuing it would be bound to pay the medical officer for such attendance such sum as they or the Local Government Board may think fit. In my opinion this would very fairly meet the evil, and I think there should be no difficulty in having it carried out either by the action of the Local Government Board, or, if necessary, a short Act of Parliament.

ANOTHER DISPENSARY DOCTOR.

BALLINAKILL DISPENSARY.

A MEETING of the Ballinakill Dispensary Committee was held, for the purpose of considering a communication from the L. G. B., respecting the medical officer's residence.

Mr. Comerford read communications which were received from the L. G. B., respecting the residence of the medical officer out of the dispensary district, of which following are abstracts:—

6th December, 1875.

SIR,—The L. G. B. desire to inform the committee of management of the Ballinakill dispensary district, that they have received a report from their Inspector, Mr. Hamilton, in which he stated that he visited the dispensary on the 18th ult., and that up to twelve o'clock, noon, the medical officer had not attended, the hours of attendance being from ten to eleven o'clock, a.m.

Mr. Hamilton was informed that the medical officer resides in the Abbeyleix district, and I am to request that the L. G. B. may be informed whether the medical officer resides within the Ballinakill dispensary district.

20th December, 1875.

SIR,—I am directed by the L. G. B. to acknowledge the receipt of your letter, and to state that they do not think it is for the interest of the sick poor that the medical officer should reside out of his district.

The medical officer stated in reply to the query of his intended residence if his appointment be approved, "Ballinakill;" in reply to query "distance of his intended residence from centre of his district," "as central as possible." Distance of such residence from dispensary building, "quite convenient." These replies were accepted by the L. G. B. as made *bona fide*, and therefore they sanctioned the appointment. The L. G. B. must therefore require the committee of management to call upon the medical officer to provide himself with a residence in his district with the least possible delay.

10th January, 1876.

SIR,—I acknowledge receipt of your letter of the 3rd inst., and I am to request that you will be good enough to summon an extraordinary meeting of the committee, in accordance with Article XI. of the Dispensary Regulations, for the purpose of considering the Board's letter of the 20th ult., and calling upon the medical officer to provide himself with a residence within his district.

7th February, 1876.

SIR,—I acknowledge the receipt of your letter of 1st inst.

I enclose queries to be answered respecting the person who has been appointed to act as temporary medical officer, during the illness of Dr. Walsh, and request that his certificate of registration under the Medical Charities Act may be forwarded to this office with replies to queries.

With reference to the above letter the Hon. Secretary stated he had since received a communication from Mr. Hamilton, regretting he could not attend.

Mr. Comerford thought their business was marked out for them, and that was to call upon the medical officer to provide himself with a residence with the least possible delay. He had prepared the following letter, which would probably meet with the approval of the meeting :—

Ballinakill, 25th February, 1876.

SIR,—I am directed by the committee of management of the Ballinakill dispensary district to notify to you that they have been required by the L. G. B. to call upon you to provide yourself with a residence in this dispensary district with the least possible delay.

I am further directed by the committee to state that such residence must be in the town or townland of Ballinakill, in accordance with the conditions of your election.

By order of the committee,

C. COMERFORD, Secretary.

The Chairman said this matter about the residence had been carrying on long enough, and it was time to put an end to it.

Mr. Hayden asked where would Dr. Walsh's successor get a house, supposing Dr. Walsh went away.

The Chairman said he might get it where he liked. That was not their business.

Mr. Comerford was directed to send the letter he had drawn up to Dr. Walsh.

ATHY UNION.

CLERK.—Dr. O'Neill has rejected a certain medicine supplied by the contractor as not being pure.

Dr. O'Neill.—I found that a certain medicine that the contractor was supplying was not made up in accordance with the Pharmacopœia. In the making up of the medicine a cheap ingredient had been substituted for the pure one.

The Chairman.—What would you advise us to do, doctor?

Dr. O'Neill.—I would advise you to order the pure medicine from Dr. Williamson, and charge the contractor with the difference in the price.

Ordered—"That the medicine be procured from Dr. Williamson, and the contractor surcharged with the difference in price; also that he be informed that if a recurrence of the matter took place, more serious measures would be resorted to."

Query.—Who is the contractor? Is he Les-lieable to make a mistake than any other trader in drugs?

REPORT OF THE INSPECTORS ON THE LUNATIC ASYLUMS IN IRELAND.

(Continued.)

Proportionably, as might be fairly supposed, the largest complement of the insane in workhouses belong to the metropolitan and other urban districts. In the Richmond, which comprises the city and county of Dublin, Louth, and Wicklow, the united classes referred to, and all considerately treated, amount to 487, of whom 228 are supported by the borough. In the Belfast, or county Antrim district, there are 293—173 being in the borough poorhouse, where a commodious pile of buildings has been lately allocated to them by the board of guardians, and a large airing court, but not as yet safely laid down. In the Limerick lunatic district there are 162 patients in unions, 84 of them in the city. The Cork district at large in its various poorhouses contains 318 mentally affected, 124 belonging to the city.

The aggregate of individuals of both sexes in the four districts just named reaches 1,260. The difference of 1,880 in the total of 3,140 becomes divisible among the other eighteen districts, comprising between them twenty-six counties and 118 workhouses, to each of which latter, if equally apportioned, 16, be they idiots, imbeciles, demented, or epileptics, would be chargeable.

If not impossible, it would be very difficult indeed, and in point of fact of little practical use, to arrive at the exact amount which 3,140 insane located in no definite mode and under no fixed regulations in 153 workhouses cost during the year for their immediate maintenance, entailing as they do a very fractional portion of the general expenditure, and the more so as not unfrequently we find them diffused through these establishments, mixed up with, and living among the ordinary paupers. Taking, however, one union with another, from local inquiries we compute that £11 a head would in round numbers be the closest approximate calculation, if so, the expenditure on them as a body in 1874 might be set down at £34,450; whereas were they resident in district asylums, they would have incurred an outlay of £79,160, the cost therein of each patient, including the rate in aid of £10 8s., being £25 2s. for that year.

PRIVATE ASYLUMS.—The same approximation of numbers as already mentioned in the lunatic population generally of Ireland, is alike noticeable in detail, as regards the respective patients in private licensed houses at the termination of 1873 and 1874; in the former year there was 664, in the latter 672, a circumstance tending to show that the statistics of insanity collected by us may be fairly deemed trustworthy, and that taking the proportion of the mentally affected to those of sound mind, while no material change or increase in the inhabitants of this country takes place, as recently has been the case, no marked variation is likely to occur in these two marked sections of society—admissions into private asylums would seem to be in close proportion to discharges by the latter under the head of recoveries generally, or of deaths.

The history of private or of public lunatic establishments from one year to another must of itself be monotonous, for properly organised, and subject to constant supervision at all seasons and at all hours there can exist but limited material for discussion; in fact the less that is afforded to discuss the more satisfactory may their operation be regarded. The statute 5 and 6 Vic., cap. 33, affords facilities for securing, so far as the executive is concerned, the protection and well-being of the registered insane of all classes.

In some respects however, the benevolent and curative objects which ought to characterise the working of private licensed houses cannot be fully attained, as the law at present stands in this country. A similar power to that which the English Commissioners in Lunacy possess, should be extended to the Inspectors, of letting out patients on trial, thereby affording them, for a definite period and with certain restrictions, the advantages derivable from a change of residence and association. Protected from legal responsibilities, and liable to be again placed under asylum treatment if not unreservedly discharged, no danger could accrue to them. We trust that the intended measure of the Chief Secretary on this impartant point and other collateral improvements will be enacted in the present session.

During the year under review, private asylums in Ireland on the whole have been satisfactorily conducted, and their inmates kindly and considerately treated; we have to record no case of harshness or personal neglect on the part of proprietors or attendants, neither are we aware of an instance—indeed one could not well occur from the frequency of our visits, and the uncertain periods at which they are made—of an unwarranted detention, so far at least as we could form a correct opinion; on some occasions, however, we noticed irregularities of forms or procedure which had to be rectified.

To be continued.

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING MARCH 4, 1876.

Total registered deaths in Dublin and suburbs * ... 233
Ten years average of same week 181

Excess of mortality above average 52
Ratio of deaths, suburb of Rathmines ... 10 per 1,000,
" " " Donnybrook† 55 "
" " " Blackrock ... 29 "
" " " Kingstown ... 11 "
" " Entire Dublin district ... 39 "
COMPARATIVE RATIOS—London ... ... 23 "
" " Glasgow... ... 34 "
" " Edinburgh ... 25 "

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

Zymotic diseases caused 32 deaths. Of these, 8 were ascribed to fever (2 typhus, 4 typhoid, and 2 simple continued fever), 11 to whooping-cough, 3 to scarlet fever, 2 to croup, and 1 each to measles, erysipelas, influenza, diarrhœa, &c.

Twenty-one children died from convulsions.

Forty-nine deaths resulted from bronchitis, 7 from pneumonia, 2 from pleurisy, and 8 from lung disease unspecified.

Paralysis caused 3 deaths, apoplexy 1, and brain disease unspecified 4.

Heart disease proved fatal in 12 instances, aneurism in 2, kidney disease unspecified, Bright's disease, cystitis, hepatitis, and jaundice, each in 1, and liver disease unspecified in 2.

Phthisis was the cause of 22 deaths, hydrocephalus of 5, and mesenteric disease of 3.

One death was the result of an accident, and another was suicidal.

Eighty-seven of the persons whose deaths were registered during the week were under 5 years of age, and 59 were aged 60 and upwards, including 36 persons aged 70 and upwards, of whom 7 were octogenarians, and 1 (a female) was stated to have been aged 95 years.

Five deaths from scarlet fever, 2 each from fever and diphtheria, and 1 from diarrhœa were registered in Belfast.

ENORMOUS ABSCESS OF KIDNEY CURED BY INCISION AND DRAINAGE.

DR. J. F. HEUSTIS (*Amer. Journ. Med. Sciences*, Oct., 1875) reports the following: A young man with abscess of the kidney suffered so greatly from the discharge of the purulent matter by the urethra, that the abscess was freely opened in the back. About three pints of fœtid pus was at once discharged. A drainage tube being inserted, the abscess was washed out daily. Soon he began to gain in general strength, the cavity to diminish in size, and the discharge to grow less. After about four months he completely recovered, excepting a small opening with slight discharge.

ON LIGATURE OF THE POPLITEAL ARTERY WITH AN ANTISEPTIC CATGUT LIGATURE. (a)

By Professor TYRRELL,

Surgeon Mater Misericordiæ Hospital, Dublin.

On Friday, December 12, 1873, I read to this Society a paper on the cure of popliteal aneurism by ligature with antiseptic catgut, and I then ventured to state that it would prove of great service in the treatment of external aneurisms. It has been frequently used in London and elsewhere, but as far as I can make out, no surgeon in Dublin has ligatured an artery in its continuity with the antiseptic ligature but myself. At least there is no published record of any such proceeding.

Before entering upon any discussion upon the merits of the plan, I shall, with your permission, lay before the Society the details of another case of popliteal aneurism cured by the antiseptic ligature.

J. Delahunty, a strong, healthy-looking countryman, æt. 55, a shoemaker by trade, was admitted under my care on the 27th July, 1874. He was recommended to me by my friend Dr. O'Connell, of Templemore, who had diagnosed the disease, and wrote me all the particulars he knew of its origin and progress.

The aneurism was on the right side, and of considerable size. The skin over the tumour was tense, and dusky in colour, and the pulsation could be distinctly seen and felt. Pressure on the femoral artery completely arrested it. As the aneurism was a very long one, I took the following measurements :—

Greatest circumference in flexed position, 16½ inches ; in extended position, 15½ inches. The left leg measured at corresponding points in both the flexed and extended positions, 12 inches ; the right limb above the patella, 14½ inches ; the left, 13½ inches.

The area of pulsation measured diagonally, posteriorly, and laterally, 9½ inches ; vertically, 5 inches. The limit of pulsation above the flexure of the joint.

The patient stated that about six months ago he had noticed a slight swelling of his instep, and suffered from pain of a throbbing character in his ham, and that the pain gradually increased. About three weeks before he came to Dublin he for the first time noticed the swelling in his ham.

On admission the foot and leg were œdematous, and hot and painful, particularly at night.

There was no history of injury or syphilis. There was no indication of any visceral disease.

The treatment at first was pressure ; it was commenced on the 3rd of August, and at first he bore it very well, and expressed himself greatly relieved of pain by the application of the compressor. The relief did not continue long. Various instruments were used, and digital pressure was most carefully kept up for twenty-four hours consecutively without the slightest permanent effect on the consistence or size of the aneurism. On the 10th the patient became very restless, fidgetty, and nervous, and on the 15th he refused to submit to any further pressure, as he said it was making him worse, not better. I therefore determined to ligature his femoral artery as soon as I had quieted his nervous system. Muriate tincture of iron, tincture of iron and morphia, in small doses, were given for a few days, and on the 25th of August I tied the artery in the usual place with a stout piece of carbolised gut. The sheath was opened barely sufficient to allow the needle unarmed to be passed under the artery. The vein was not seen. Parenthetically I may remark that the parts are much less disturbed when the needle without the ligature is passed round the vessel and then threaded and withdrawn, than when it is threaded before it is passed ; consequently it is the mode that should be always adopted when practicable.

The wound was sponged with a solution of chloride of

(a) Communicated to the Surgical Society of Ireland, Mar. 3. The discussion will be found on page 236.

zinc (gr. 20 ad ℥i.), the ends of the ligature cut short, the edges brought together with gut sutures, and the dressing completed with a pad of tenax rolled in muslin, and a bandage. It is unnecessary, and indeed would be quite unsuited to this Society, to give any details of the after-treatment. Suffice it to say that the wound healed nearly through its entire length by the first intention, and that no trace of the ligature ever appeared.

He was disharged on the 3rd of October quite well; the tumour had reduced to about the size of a billiard-ball, and was quite hard. Shortly afterwards I had a letter from Dr. O'Connell stating that Delahunty had resumed work, and did not suffer any inconvenience from the operation.

I would have laid this case before the Society last session had not a protracted illness prevented me.

At present there is a good deal of discussion in London and elsewhere as to the best mode of tying arteries in their continuity. Many surgeons use catgut in preference to silk or hemp, and the question is, Is it better than silk or hemp? If it is, in what respect? With what force should it be tied? Do we wish to lacerate the inner coats of the artery or not?

As far as I can form an opinion from what I have read, and from the confidence my two successful cases have given me, although I do not speak dogmatically, I believe with Holmes, that the catgut ligature is a most efficient agent in combating the tendency to secondary hæmorrhage, and that it renders possible that union by the first intention which was John Hunter's object in his first operation on the femoral artery.

A very interesting discussion took place on this subject at a meeting of the Clinical Society of London on the 12th of last November, in which Mr. Maunder, Mr. Holmes, Mr. Callender, Mr. Heath, and others took part, and which is fully reported in the *Medical Times and Gazette* of the 27th of November.

As to the amount of force to be used, it seems that sufficient to occlude the artery and allow the formation of a clot, without dividing the internal coat on the one hand, or causing sloughing or ulceration of the external coat on the other, would be what is desirable; but that must be attained by practice.

In a case reported by Mr. Holmes, after death the artery was perfectly continuous; the knot of the ligature was visible, but there was nothing to be seen of the rest of the string.

I cannot sit down without alluding to Mr. Pemberton's Birmingham) case bearing on this subject, published in the *Lancet* of last Saturday.

CASE OF LITHOTOMY. (a)

By J. K. Barton, M.D., F.R.C.S., &c.,
Surgeon to the Adelaide Hospital.

R. W——, a tall country lad of 19 years of age, was sent up from the co. Cavan by Mr. —— to the Adelaide Hospital with symptoms of stone in the bladder. He was admitted upon the 22nd of June, 1875. He gave the following *history* of his case: In the first week of January, 1875, he for the first time began to suffer from any urinary trouble; what attracted his attention was that the stream of urine, as he passed it, suddenly stopped; it then went on again. Soon after he first noticed this, he passed a little blood, after he had finished making water. In February he was passing water frequently, 7 or 8 times in the day, and also at night several times; and more than once at this time the water stopped altogether, and he could not pass any. This frequency and urgency continued to increase up to the time of his admission, in spite of all remedies employed. His state on admission was as follows: He is obliged to pass water about 15 times during the day, and 8 or 10 times during the night. He gets but little sleep in consequence. The stream is checked suddenly while flowing, and then he suffers severe pain.

The urine contained pus and ropy mucus, natural sp. gr. Under the microscope a very large quantity of crystals of triple phosphates were visible. A Thompson's sound at once detected a stone, the click being audible to all those standing round the bed. No blood was passed after the introduction of the sound, but micturition was very frequent during the following night. He was ordered a hot bath and a morphia suppository.

Upon the 25th micturition was not so frequent, but not less than 8 times during the night. A second sounding was made, and the stone found to be rough, and of medium size.

Upon the 27th a small rigid lithotrite was passed, but it caused great irritation, and the stone was not caught.

July 2nd.—Micturition was very frequent, the urine was high-coloured, and depositing copiously both pus and ropy mucus.

Under these circumstances I decided on lithotomy, and on the 14th of July performed the lateral operation. When my finger entered the bladder I felt no stone, and I had a second or two of anxiety; but by passing my finger as far as possible I felt it, in the fundus, where it had been pushed before the point of the staff. The outer phosphatic layers broke down under the grasp of the forceps, and it was only after considerable delay I extracted by means of the scoop the irregular stone which I now exhibit, weighing, counting all fragments which could be collected, 2·50 grs. The bladder having been carefully washed out, a canule à chemise was introduced, and the patient removed to bed. There was no hæmorrhage worth mentioning. A pill containing gr. i. of opium, gr. i. of camphor, and ½ gr. of ext. of belladonna was given at bed-time, and continued with good effect each night for a week or more.

Next day he was going on well, scarcely any pain. Urine was coming through canula; contains a good deal of mucus, pus, and some phosphatic grit.

Upon the 18th the canula was removed, and the bladder washed with the biborate of soda, and a glycerine lotion through the wound. This was repeated every second day, the urine still containing both pus and mucus, until the 2nd of August, *i.e.*, 9 days after the operation. He had a severe rigor, and accompanied by a sudden rise of temperature, pulse 120, very full, skin hot and dry. He complained of pain over the bladder, but the pain was not localised, but was present over the lower part of the abdomen. He took a mixture containing 5 drop doses of tincture of aconite, with aqua amm. acetatis, every hour. This seemed to cool him, so that on the 3rd his pulse was 115, and temperature 102·6°. The night had been sleepless.

Upon the 4th his temperature was 101°, and pulse 110; and on the 5th both were normal. Upon this day he passed a little water through the penis

Upon the 24th he left the hospital, passing water freely through penis, the urine containing only a little more mucus than natural. He could then keep his urine about two hours without inconvenience; wound all but healed; no urine coming by it.

I heard of him since that he was quite well.

(a) Communicated to the Surgical Society of Dublin, Mar. 3. The discussion will be found on page 236.

CASE OF OVARIOTOMY. (a)

Under the care of H. G. Croly, F.R.C.S., &c.,
Surgeon to the City of Dublin Hospital, &c.

Mary Hennessey, æt 40. Residing at Ballintubber, county Limerick. Never married. Admitted into the City of Dublin Hospital on February 18th, 1875.

History.—Was always in the enjoyment of good health up to *two* years ago, at which time she was attacked with something like "the gravel." Since then has been in

(a) Communicated to the Surgical Society of Ireland, Mar. 3. The discussion will be found on page 237.

delicate health. Menstruation always quite normal in every respect, until the *second* last time, when it was very profuse, lasting *fourteen* days, and accompanied by considerable pain in the left side. About six months ago noticed that she could not stoop or lift anything from the ground without causing pain of a dragging character. In a few days after this she felt a tumour in the right side, which has gradually increased in size up to the present. For the last two months, just before menstruation would appear, she was seized with pain and a feeling of distension in the tumour, which disappeared as soon as menstruation ceased. Latterly has been seized with stinging pains in both sides, lasting only a few seconds, increased greatly by breathing.

On Examination—There is a smooth round tumour, dull on percussion, and clear at the base towards the lumbar regions, occupying the whole of the abdomen, with some varicose veins ramifying on its surface.

Measurement.

At umbilicus	37¾ inches.
From ensiform to pubis ...	16½ ,,
,, ,, umbilicus ...	7 ,,
,, umbilicus to pubis ...	9½ ,,
,, ant. s.s. right side to umbilicus	10 ,,
,, ,, left ,, ,,	10 ,,

March 8, 1875.—Menstruated for the first time since admittance into hospital; lasted for five days, and had a tendency to menorrhagia, and was painful for the first two days. She fancies the swelling has reduced in size, and sleeps better at night. Had a little difficulty in breathing for the first two or three days after being admitted into hospital.

Measurement.

March 19.—	
At umbilicus	39 inches.

,, ,, umbilicus ...	7½ ,,
,, umbilicus to pubis... ...	9½ ,,
,, right ant. s.s. to umbilicus ...	10 ,,
,, left ,, ,, ...	11 ,,

April 15.—Menstruation due, a week over usual time. Feet and legs swell after sitting up. No albumen in urine. Had a stinging pain in right side under the ribs about a fortnight ago, which has now entirely disappeared.

Measurement.

At umbilicus	40⅛ inches.
From ensiform to pubis ...	18 ,,
,, ,, umbilicus ...	8½ ,,
,, umbilicus to pubis ...	10 ,,
,, right ant. s.s. to umbilicus ...	10⅛ ,,
,, left ,, ,, ...	11 ,,

Clinical Records.

CASE OF RINGWORM OCCURRING IN AN INFANT WITHIN SIX HOURS OF BIRTH.

By J. Roche Lynch, L.R.C.P.

The following history exhibits, in my experience, the earliest period in a child's life, on record, in which ringworm has appeared; save this, there is nothing very especial in the case: but to some of your readers, particularly those interested in skin diseases, it may be of interest.

On the 16th of January, 1874, I was called upon to attend Mrs. W. in her confinement. She has had two children, both living. This child was born at 2 p.m., and the same evening, a friend calling on a visit, noticed a small red spot on the child's right cheek, three-quarters of an inch below the eyelid. I was shown it the next day, but paid little attention to it, conceiving it to be of no importance. It, however, steadily increased, and on the 11th of February was about the size of a shilling. I now recognised it as a ringworm presenting the ordinary conditions. It was treated with the application of acetic acid, and in three weeks it was quite cured.

On inquiry of the nurse, I found four days before Mrs. W. was confined, that she (the nurse) had visited some friends, where one of the children was suffering from ringworm. She took the child for a short time upon her knee. This appears to be the secret of the case; but I must admit for a moment that the question rose in my mind, "Could it be congenital?" On consideration, however, it did not appear tenable; but until I extracted the history of the visit from the nurse, I was puzzled how to account for the disease. I afterwards discovered that at the time she dressed the newly-born infant she was wearing the same dress as on the visit. This was of black stuff, one to which particles of any kind might cling. I concluded that a spore or spores of the fungus had fallen from the head of the first child, and retaining vitality, settled on the cheek of the infant, probably when first handled by the nurse. From this it appears that the spores retain their activity for at least four days, and that when they meet with a suitable locality, develope such power as to produce a clearly defined spot in the course of what certainly did not exceed six hours.

It seemed to me advisable to publish the case, as it may possibly be of some service to those connected with schools and large institutions, which are sometimes sorely troubled by the pest, and points to the necessity of destroying effectually any material that may retain the *débris*, or at least of subjecting it to the influence of such means as will interfere with its inherent vitality, to say nothing of immediate isolation.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

This Society met on Friday, March 3rd, 1876, Dr. Kidd, Vice-President of the College, in the chair.

STRANGULATED HERNIA.

Mr. Croly exhibited a specimen which he had removed from a woman who died in the City of Dublin Hospital on Sunday morning last. She was admitted on the previous evening, suffering from strangulated femoral hernia at the right groin. The woman was very much collapsed; she was 50 years of age, and stated that the tumour was in the groin for a year, partly reducible, but there was a portion of the tumour which was never reducible. In consequence of the great state of collapse in which the patient was on admission, he was afraid to perform the operation on her, and he had to wait until the following morning, and he tried every means to bring about a certain amount of reaction. However, on Sunday morning the pain in the abdomen was so intense that, though he did not entertain any hope of her life being saved, he performed the ordinary herniotomy operation. He first tried if he could reduce the tumour, but found he could not do so. He then opened the sac and found a large piece of omentum—which was much smaller now—and on throwing up this large piece of omentum there was a small knuckle of gut of a very livid colour, though not gangrenous, constricted at the upper part of the splenic opening. He reduced the tumour, but the poor woman died in an hour and a half after the operation. On making a post-mortem examination he found extensive peritonitis where the tumour was strangulated from the Wednesday evening previously. There was now no trace of peritonitis, but it was very well marked at the time of the post-mortem examination, where the small knuckle of gut was tightly nipped. He thought the specimen was worth showing, because it was one of those cases that they all met with, and that they must all feel great regret at not getting in time. These cases were either treated by the taxis too long, or else they were overlooked, or the patient declined to allow the performance of the operation from some cause or other. The patient in the case he had detailed evidently died from the result of shock or peritoneal inflammation.

Professor TYRRELL then read his paper,

LIGATURE OF THE POPLITEAL ARTERY,

which will be found on page 233.

In the discussion which ensued,

Mr. STOKES thought the Society was indebted to Professor Tyrrell for his highly interesting communication. He believed Professor Tyrrell was quite correct in stating that he (Professor Tyrrell) was the first surgeon in Dublin who applied the carbolised catgut ligature to an artery in its continuity. He (Mr. Stokes) had applied ligatures, both of hemp and silk, and had also applied what had been termed the temporary deligation. In none of these cases did he obtain union by the first intention, and his only object in addressing the meeting was to ask Professor Tyrrell a question—whether he obtained union by the first intention in the case in which he applied the carbolised catgut ligature to the femoral artery in its continuity? He thought that if Professor Tyrrell had done so it would form a very strong argument in favour of their adopting that method of treatment in cases similar to the one Professor Tyrrell had described. He hoped Professor Tyrrell would inform the Society on the point.

Mr. CROLY said he had no experience in ligaturing arteries by carbolised catgut in the way that Professor Tyrrell had laid down, and had not tried it for aneurism, because he had not adopted that plan. But with regard to one point that Professor Tyrrell mentioned, relative to the laceration or non-laceration of the coats of the arteries, he (Mr. Croly) dared say that Mr. Tyrrell would recollect that Scarpa laid down many years ago that it was not necessary to lacerate the internal coats of an artery when applying the ligature, but merely to approximate the internal coats. It would appear worth going back to Scarpa's mode of non-laceration of the coats.

Professor TYRRELL said, in reply, that he wished to remind Mr. Croly that Scarpa, in his early operations, was in the habit of tying two catgut ligatures. He did not know that that was continued afterwards. It was his (Mr. Tyrrell's) object merely to note that laceration of the internal and middle coats was looked upon as a *sine quâ non*. With regard to what Professor Stokes had said, the wound healed up in its entirety, and the part that did not heal up was not the part where the ligature was placed. He had no trouble with the wound at all; the only difficulty he had was to keep the patient in bed. They got well when the aneurism was tied,—all pain ceased and all inconvenience—except the anxiety lest anything should go wrong. If they read Mr. Pemberton's case and the discussion which took place at the Clinical Society of London, they would find that the plan of treatment he had described deserved a trial; not that he would wish to say that it should supersede what was familiarly known as the Dublin method. Everyone who had anything to do with patients knew that they could not tell what a patient would submit to, and that what would be good for one would not answer for another. He had a case in which a man had a femoral aneurism. He (Mr. Tyrrell) applied the catgut ligature, and suddenly it got well unknown to them. Delahunty was anxious to get back to his business, and finding that he was not getting well, he became very irritable, and positively refused to have anything more to say to pressure. Having had experience of the ligature, he (Mr. Tyrrell) put it on. A surgeon-major in the Guards ligatured the external iliac artery not very long since with catgut ligature, and, just as in his (Mr. Tyrrell's) case, he put on a double catgut ligature, and he heard no more about the case. He did not wish to say that this mode would supersede pressure, but still he thought it was a means which was well worthy of attention, and of being practised when they had to deal with aneurisms which must of necessity be tied.

Dr. BARTON then read his paper on

LITHOTOMY,

which will be found on page 234.

In the discussion which followed,

The CHAIRMAN said the paper of Dr. Barton was a most important one, and presented many points well worthy of the consideration of the Society.

Mr. TYRRELL said that, from the fewness of the calculi in Dublin, he was not surprised at some hesitation being manifested among the members present to rise and speak on the subject. He had very little experience indeed, having had only two cases of stone, but he had always been surprised that surgeons should introduce the tampon, or *canule à chemise* in inflammation of the bladder. It was not to prevent the urine becoming extravasated, because the water would flow with the catheter, no matter what they did with regard to the urethra. In India they did not think of introducing the *canule à chemise*. They did not introduce it at all unless hæmorrhage occurred and they were desirous of stopping it. In the case he had operated upon he never thought of introducing it, nor would he do so in future unless it were necessary for the arrest of hæmorrhage, and he believed that if they had any foreign body when a state of irritation existed, it certainly did not tend to allay that irritation by leaving the catheter there. They had so little experience in Dublin that they could hardly hope to become authorities on the subject of calculi.

Professor STOKES said that, with reference to the last observation of Professor Tyrrell's he (Mr. Stokes) had always introduced the *canule à chemise*, and he had never seen any harm come from it, nor in any case in which he had seen other surgeons perform the operation who made use of that instrument. Certainly in his (Mr. Stokes') cases he introduced it not to stop any immediate hæmorrhage, but in the event of any secondary hæmorrhage occurring afterwards. It was certainly, he believed, a means of protection, and of stopping the hæmorrhage, and for that reason he thought it should not be thrown aside, particularly when they always bore in mind that, certainly in his experience, and he believed in the experience of most surgeons present, it was not attended by any unpleasant consequences, or in any way interfered with the subsequent favourable progress of the case. Therefore he certainly would not agree with Professor Tyrrell when he said that the instrument should be abandoned by surgeons in this operation.

Mr. B. WILLS RICHARDSON remarked that he did not think that Professor Tyrrell meant to convey that the instrument should be abandoned, but that it should simply be reserved for cases in which hæmorrhage occurred. (Mr. Tyrrell: Hear, hear). He (Mr. Richardson) did not think it was advisable to introduce the instrument otherwise. In the last case he had he did not introduce it. He recollected, too, that the late Mr. Smyly was against using the instrument unless hæmorrhage threatened or supervened.

Mr. CROLY said it was well known that stone was comparatively rare in Ireland. He had performed latterly lithotomy and lithotrity more than once. He had published seven cases of stone in the journals. When recently in London he was greatly surprised to learn from Mr. Bryant and other eminent surgeons in the large London hospitals that they had very few stone cases now, because a hospital had been established for the treatment of stone, and it monopolised all those cases. When they remembered Mr. Cronyff's time, and also Sir Philip Crampton's, if their cases of stone were put together, considering the size of the country, it was not so very rare in Ireland. It was of course rare compared with India and some parts of England. With regard to the question of lithotomy and lithotrity, that was one of the nicest points in surgery. He remembered a case which he had, a man from Enniskillen, some five years ago, and the great difficulty he found was, whether he would cut him or crush the stone. The man had irritability of the ureters, and got rigors from the introduction of instruments. He cut that man, and had every reason to be satisfied with the result of the operation. With regard to the tampon, or *canule à chemise*, he remembered that in the first case in which he used it, it answered admirably, but in the second case it seemed, after the first few hours, to act as a foreign body, and then he took it out. He had used it in every case of stone he had, but he thought that it did sometimes produce irritation. The object of using it was to be prepared to arrest hæmorrhage if it should occur. There could be no doubt that the difficulty of introducing the canula subsequently for the purpose of arresting hæmorrhage would be very great. The question of using the canula was just a matter of experience with surgeons, and that sometimes it might seem to answer very well, He was inclined himself to introduce the canula, and if it produced irritation and there was no hæmorrhage after the first few hours it made its own way out.

Mr. TUFNELL said he had seven or eight cases of stone, and had been very fortunate with them, never having lost a case. He had always used the *canule à chemise*, and the great point was to introduce it fairly and fully into the bladder, so that it made a free exit for the urine. He was in favour of the

instrument, and he never saw any disadvantage follow its use. It loosened itself in 36 or 40 hours and came away.

Dr. Hy. Kennedy said, in reference to the question raised by Mr. Tyrrell as to the frequency of stone in this country, he might remark that the paper of Sir Philip Crampton recorded some 100 cases of lithotrity. As far as he (Dr. Kennedy) knew, from the literature of the subject, stone in the bladder was not so rare comparatively.

Dr. Barton, in reply, had only to say that the reason he introduced the canula in the case he had recorded was to give free exit, to insure a perfectly free exit for the urine, which was sure to be loaded with pus, mucus, and lithites, and some phosphatic grit to some extent; and it certainly caused no irritation in this particular instance. As far as that case went, he thought it did not argue against its use. The only other remark that he would make was that he believed there was considerable experience in the records of surgery in this country in the old *Hospital Gazette* and the *Dublin Journa* of lithotomy; at all events, of what other surgeons had experienced. The special point to which the case pointed was the advisability of setting an inflamed bladder at rest for lithotomy, and that had not been much touched upon by any of the speakers. That was the chief point of interest in the case.

Mr. Croly then read his paper on

A CASE OF OVARIOTOMY,

which will be found on page 234.

In the discussion which ensued,

The Vice-President said he saw the operation performed, and also saw the woman prior to the operation, as well as on one occasion during her subsequent treatment. The case certainly seemed a very favourable one for operation. He did not know that any of those who saw the case diagnosed the great adhesions that were present, though it was a point that he believed was the universal experience of surgeons that they had no means of doing at present. In this case they were very general and very deeply situated, and there was a very great difficulty in separating them. With regard to this point of adhesions, he believed that they should not attach too much importance to them. Anterior adhesions especially affected the result of the operation, and posterior adhesions—adhesions to the liver or diaphragm did not seem to affect it very much either, but adhesions down through the true pelvis were very much more serious obstacles, both to the removal of the tumour and the success of the operation. Fortunately they could very frequently diagnose adhesions in that situation when they could not in other situations. He thought Mr. Keith had made the remark that cases in which the adhesions were most general very often succeeded the best afterwards, but the character of the peritoneum, he suggested, was so altered by adhesions that it ceased to be a serous membrane and became more of the character of connective tissue than true serous membrane, and consequently was less liable to take up inflammatory action. In some cases at which he had been present he certainly had seen the worst results occur where there was a total absence of adhesions. He remembered one case where the sac was removed through an incision perhaps not more than two inches in length. It came out quite easily, and there was not a single adhesion, yet that patient began actually to die upon the table; her pulse ran up, and she died within some twenty-four hours after the operation. In other cases, where they had had great trouble in detaching adhesions and considerable hæmorrhage from the torn surfaces—so much so as to require the application of the actual cautery to check that hæmorrhage—they had recovered without a bad symptom. It was very interesting to him to see this woman after the operation. He never saw any patient after a serious operation exhibit so little constitutional trouble she had done after the operation. She expressed herself as exceedingly comfortable; she lay perfectly at ease, and took the nourishment that was allowed her, which was of course very light and mild in character. She took it well, and suffered neither pain nor discomfort.

Dr. Denham said he had the privilege of seeing this patient before the operation and afterwards. He fully concurred in the propriety of the operation; but he went away almost wishing that he had not given his sanction to its performance, from the amount of difficulty that Mr. Croly experienced in separating the adhesions, and more particularly from the fact of the intestine being glued to the sac, and being to a great extent forcibly separated from it. With regard to the operation, he had seen some of the simplest cases prove fatal, while, on the other hand, in other cases where the disease was most extensive, the women had recovered without any single bad symptom. He thought the case was one of very deep interest indeed practically, and reflected the greatest credit, not only on Mr. Croly, but on the pupils of the hospital. He (Dr. Denham) believed that a vast deal of success depended on after treatment. Mr. Keith never operated in an hospital; he never operated without a certain staff of nurses and assistants, who always accompanied him, and he attributed a great deal of his success to that fact—of having a large airy room, and always the same attendants, who are accustomed to the treatment of such cases. He (Dr. Denham) believed Mr. Keith's practice was not to sew up the wound, but he left it open with a sort of small tube attached to it.

Dr. Kidd remarked, with regard to the attachment of the intestine, that the liability of attachment of the intestine was the reason why they should recommend the operation in these cases. He was present at the post-mortem examination of a woman who had died from the result of an attachment of intestine to an ovarian cyst. This woman had been an outpatient at the Coombe Hospital, and she had also been in several other hospitals, where operative treatment had been recommended to her, but she would not submit to it. At the Coombe Hospital they examined the case very carefully, and, as far as they could make out, the tumour was in a perfectly quiescent condition. She had had the tumour for a number of years, and it did not seem to be growing. On the contrary, as far as they could learn from the history of it, it had ceased to grow, and did not affect the woman's general health. Consequently he did not recommend any operation. The woman seemed to him to bear it so well, her health was so little injured by the tumour, that her chances of life without the operation were a great deal better than would be the case if it were performed. For that reason he did not recommend the operation. However, a few months afterwards she got symptoms of obstructed intestine, and she died in consequence of the obstructed intestine—not merely from the mechanical or constitutional effects of the tumour, but from the obstructed intestine. On making the post-mortem examination they found that a coil of the small intestine was closely adherent to the tumour, and bound down by a band of lymph to it, so that the passage of the intestine was obstructed. She had a great amount of flatus, and he remembered that part of the intestine above the band of adhesion was in a state of strangulation, and that was what made him more inclined for operative interference where a woman died in that way. If he were to meet with a slow-growing case again, the liability of death occurring from the attachment of a coil of intestine would induce him to recommend the operation more than otherwise.

Professor Stokes, who also saw the operation, said he left the operating theatre under the impression—looking at the great difficulties that were experienced, and the number of adhesions in the case—that in all probability it would follow the example of some of the other cases that had been operated on in this city; and it was with a sense of unmixed satisfaction that he heard that the case was brought to a successful termination. It was not too much to say that the case was a trial of surgical skill; and it was most gratifying to know that such a favourable result had been brought about. He was glad the subject had been introduced, because it enabled him to mention two cases in which he had performed the operation of ovariotomy, but unfortunately with results unlike the one under notice. In both cases he had the pleasure and advantage of the Vice-President's assistance; and the cases were apparently favourable cases, at least, as far as in their power lay to give an opinion with regard to such cases. She was a female aged 23 years, and the other patient was 35 years of age. The cysts were not very large. In other respects the patients were in good health, fresh complexioned, well nourished, and no great difficulty was experienced in either operation. In one of the cases there were absolutely no adhesions whatever. The wound made was a small one, and as he said before, there were no adhesions and no hæmorhage—in fact, everthing went on perfectly smoothly, and apparently satisfactorily. Both patients appeared to have recovered the immediate effects of the operation; and in the last case, on the next morning after the operation, the patient's pulse was 76, her skin was cool, she was inclined for food, she was talking cheerfully, and everything was apparently going on well. In that case, 26 hours after the operation, the patient's face suddenly became livid, the pulse fell, a cold

sweat burst out over her forehead, and in less than half-an-hour she was dead. On making a post-mortem examination there was no cause to be found for that sudden collapse. A similar change arose in the second case, with this difference, that in that case it was 36 hours after the operation, but a similar condition of things was observed. He was glad the subject had been brought under the notice of the Society, as it had enabled him—though he was quite unable to offer any explanation of the cause of the fatal results in these cases—to ask if anyone else had met with similar changes, and if so, could they offer any explanation of them, as he could not do so. There they had two cases in which no difficulty was experienced in operating—in one case no adhesions, and in the other very slight adhesions, and everything apparently satisfactory about the cases and about the operations, and yet both those cases died in a comparatively short space of time, without any cause that he could assign for death. It just showed that in some cases where the circumstances were such as to make them think the cases would be most unfavourable, would terminate successfully, and *vice versâ*. One observation had fallen from Dr. Denham which he (Mr. Stokes) thought deserved remark, and it was in reference to the alleged advantage of not operating in these cases in hospital. His (Mr. Stokes') impression, from what he had read, and his experience, was that a great deal too much stress had been laid on that topic, for they had had, not a large number certainly, but still there had been, as Mr. O'Grady had shown, a very considerable number of successful cases of ovariotomy treated in Dublin in which the operations were performed in hospital. A considerable number of operations had been performed in private by gentlemen who had been imported into this country to perform the operation, and in which the results had not been at all successful, and in which the operations were carried out with all the surroundings that were considered by Mr. Keith and others to be desirable. He (Mr. Stokes) therefore thought that too much stress had been put upon the point with reference the importance of isolating these cases. He remembered three or four cases in which precautions sometimes used were not resorted to, where the operation was performed in the theatre of the hospital, surrounded by a large class of students, and in which the cases terminated as successfully as could possibly have been desired.
